# **Diffie-Hellman Key Exchange**

Diffie-Hellman protocol: allows two parties to agree on a common session key: In a finite cyclic group G, of prime order p, with a generator g

$$\begin{array}{cccc} x \stackrel{s}{\leftarrow} \mathbb{Z}_p, X \leftarrow g^x & \xrightarrow{X} & y \stackrel{s}{\leftarrow} \mathbb{Z}_p, Y \leftarrow g^y \\ K \leftarrow Y^x = g^{xy} & \longleftarrow & Y & K \leftarrow X^y = g^{xy} \end{array}$$

No authentication provided

### Authenticated Key Exchange

### Semantic security / Implicit Authentication:

the session key should be indistinguishable from a random string to all except the expected players

CNRS/ENS/PSL/INRIA

David Pointcheval

2/41

# **Authentication Techniques**

### Asymmetric technique

- Assume the existence of a public-key infrastructure
- Each party holds a pair of secret and public keys

### Symmetric technique

Users share a random secret key

### Password-based technique

Users share a random low-entropy secret: password

### **Electronic Passport**

Since 1998, some passports contain digital information on a chip Standards specified by ICAO (International Civil Aviation Organization)

4/41

In 2004, security introduced:

- encrypted communication between the chip and the reader
- access control: BAC (Basic Access Control)

The shared secret is on the MRZ (Machine Readable Zone) It has low entropy: at most 72 bits, but actually approx. 40

 $\implies$  low-entropy shared secret: a password pw

David Pointcheval

**BAC: Basic Access Control** 

The symmetric encryption and MAC keys are deterministically derived from pw

From a pair  $(C_R, M_R)$ , one can make an exhaustive search on the password *pw* to check the validity of the Mac  $M_R$ After a few eavesdroppings only : password recovery

#### What can we expect from a low-entropy secret?

CNRS/ENS/PSL/INRIA	David Pointcheval	5/41

### **Off-line Dictionary Attacks**

As in the previous scenario, after having

- eavesdropped some (possibly many) transcripts
- interacted (quite a few times) with players

the adversary accumulates enough information

to take the real password apart from the dictionary

 $\implies$  Efficient password-recovery after off-line exhaustive search

For the BAC: quite a few passive eavesdroppings are enough to recover the password! How many active interactions could one enforce?

## **On-line Dictionary Attacks**

### **On-line Dictionary Attacks**

- The adversary interacts with a player, trying a password
- In case of success: it has guessed the password
- In case of failure: it tries again with another password

### **In Practice**

- This attack is unavoidable
- If the failures for a target user can be detected the impact can be limited by various techniques
- If the failures cannot be detected (anonymity, no check, ...) the impact can be dramatic

CNRS/ENS/PSL/INRIA

Seems better than BAC: no information leaks about *K*, so no leakage about *pw* either! But *K* will be later used:  $c = E_K(m)$ 

any information about m leaks about K, and leaks on pw...

 $\implies$  The security model has to deal with information leakage about K

Passive eavesdropping, even with leakage of K: secure under **CDH**! But the adversary can try to impersonate Bob, and know Z...  $\implies$  The security model has to deal with active attacks

 $Z \leftarrow Y^{x}; K \leftarrow \mathcal{H}(pw, X, Y, Z)$ 

 $Z \leftarrow X^{y}$ ;  $K \leftarrow \mathcal{H}(pw, X, Y, Z)$

### Where

- The adversary controls the network: it can create, alter, delete, duplicate messages
- Users can participate in concurrent executions of the protocol

### On-line dictionary attack should be the best attack

 $\implies$  No adversary should win with probability greater than  $q_S/N$  where  $q_S = \#$ Active Sessions and N = #Dictionary

# **Game-based Security**

[Bellare-P.-Rogaway – Eurocrypt '00]

The adversary  $\mathcal{A}$  interacts with oracles:

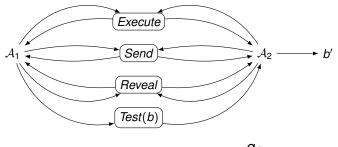

- **Execute** $(A^i, B^j)$ 
  - ${\mathcal A}$  gets the transcript of an execution between A and B
  - ⇒ Passive attacks (eavesdropping)
- Send( $U^i$ , m)
  - $\mathcal{A}$  sends the message *m* to the instance  $U^i$
  - $\implies$  Active attacks against  $U^i$  (active sessions)
- **Reveal** $(U^i)$ 
  - $\mathcal{A}$  gets the session key established by  $U^i$  and its partner
  - $\Longrightarrow$  Leakage of the session key, due to a misuse
- **Test** $(U^i)$  a random bit *b* is chosen
  - If b = 0, A gets the session key (*i.e.*,  $Reveal(U^i)$ )
  - If b = 1, A gets a random key

## Security Game: Find-then-Guess

Secrecy of the key: output b', the guess of the bit b involved in the Test-query Is the obtained key real or random?

Constraint: no *Test*-query on a trivially known key

i.e., key already revealed through the instance or its partner

 $Adv^{FtG}(\mathcal{A}) = 2 \times \Pr[b' = b] - 1 \le \frac{q_S}{N} + negl()$ 

David Pointcheval

CNRS/ENS/PSL/INRIA

# Freshness and Partnering

#### Partners

Two players are partners if they share the same Session ID Where SID should model ideal executions:

- two players with same SID's and same *pw*'s conclude with the same session key
- two players with different SID's or different *pw*'s conclude with independent keys

### Freshness

A key or a player is fresh if none of the key/player or the partner's key/player has been revealed/tested

Only fresh keys/players can be revealed/tested

CNRS/ENS/PSL/INRIA

David Pointcheval

17/41

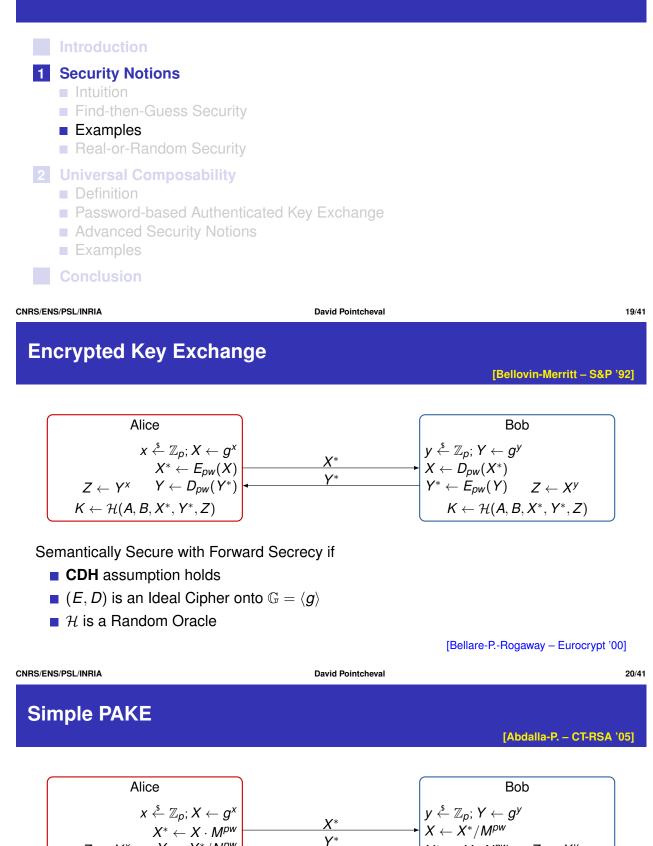

16/41

# **Security Notions: Forward Secrecy**

Semantic Security

The Find-then-Guess game models the secrecy of the key

- $\implies$  the session key is unknown to the other players
  - What about this secrecy after the corruption of a player?
  - What about the knowledge of the two players?
- Forward Secrecy
  - An additional oracle: Corrupt(U) provides the password pw of the player U to the adversary
  - A new constraint: For any *Test*(U<sup>i</sup>), player U was not corrupted when U<sup>i</sup> was involved in its session

 $Z \leftarrow Y^x$   $Y \leftarrow Y^*/N^{pw}$ 

 $K \leftarrow \mathcal{H}(A, B, pw, X^*, Y^*, Z)$ 

CDH(M, N) hard to break
H is a Random Oracle

Semantically Secure if

 $Y^* \leftarrow Y \cdot N^{pw}$ 

 $Z \leftarrow X^y$ 

 $K \leftarrow \mathcal{H}(A, B, pw, X^*, Y^*, Z)$

# Security Game: Real-or-Random

[Abdalla-Fouque-P. – PKC '05]

Secrecy/independence of all the keys: many Test-queries with the same bit b

- If no key defined by the protocol yet: output  $\perp$
- If dishonest/corrupted partner: output the real key
- If player/partner already tested (not fresh): output the same key
- If b = 0: output the real key
- If b = 1: output a random key

 $Adv^{RoR}(\mathcal{A}) = 2 \times \Pr[b' = b] - 1$ 

CNRS/ENS/PSL/INRIA

David Pointcheval

23/41

### Security Game: Real-or-Random

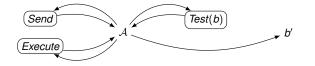

Semantic Security (Encryption)

[Bellare-Desai-Jokipii-Rogaway – FOCS '97]

Find-then-Guess and Real-or-Random are polynomially equivalent  $Adv^{RoR}(t, q_T) \leq q_T \times Adv^{FtG}(t)$ 

where  $q_T$  is the number of Test-queries

- For Password-based Authenticated Key Exchange:
  - $Adv^{FtG}(t) \leq \frac{q_s}{N} \neq Adv^{RoR}(t, q_T) \leq \frac{q_s}{N} \Longrightarrow$  Stronger notion
- No need of Reveal-queries ⇒ Simpler security notion [Abdalla-Fouque-P PKC '05]

## **Game-based Security: Limitations**

- Proven bounds: O(q<sub>S</sub>)/N, but almost never q<sub>S</sub>/N
   hard to get optimal bound!

   This means: a few passwords can be excluded by each active attack
   But q<sub>S</sub> is sometimes the number of Send-queries
   which is more than the number of Active Sessions
- Passwords chosen from pre-determined, known distributions
- Different passwords are assumed to be independent
- No security guarantees under arbitrary compositions
- → Universal Composability more appropriate [Canetti FOCS '01]

[Canetti-Halevi-Katz-Lindell-MacKenzie – Eurocrypt '05]

Real-or-Random Security

### 2 Universal Composability

### Definition

- Password-based Authenticated Key Exchange
- Advanced Security Notions
- Examples
- Conclusion

# Definition

### **Real Protocol**

The real protocol  $\mathcal{P}$  is run by players  $P_1, \ldots, P_n$ , with their own private inputs  $x_1, \ldots, x_n$ . After interactions, they get outputs  $y_1, \ldots, y_n$ 

#### **Ideal Functionality**

An ideal function  $\mathcal{F}$  is defined:

- it takes as input x<sub>1</sub>,..., x<sub>n</sub>, the private information of each player,
- **and outputs**  $y_1, \ldots, y_n$ , given privately to each player
- The players get their results, without interacting: this is a "by definition" secure primitive

CNRS/ENS/PSL/INRIA

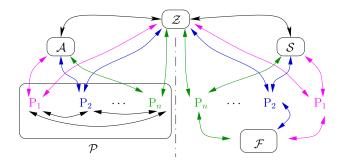

David Pointcheval

28/41

### Simulator

 $\mathcal{P}$  emulates  $\mathcal{F}$  if, for any environment  $\mathcal{Z}$ , for any adversary  $\mathcal{A}$ ,

- there exists a simulator  ${\mathcal S}$  so that, the view of  ${\mathcal Z}$  is the same for
  - A attacking the real protocol  $\mathcal{P}$
  - $\blacksquare \ \mathcal{S}$  attacking the ideal functionality  $\mathcal{F}$

CNRS/ENS/PSL/INRIA

- Conclusion

# **PAKE Ideal Functionality**

#### Queries

- NewSession = a player joins the system with a password
- TestPwd = A attempts to guess a password (one per session) The adversary learns whether the guess was correct or not
- NewKey = A asks for the session key to be computed and delivered to the player

### **Corruption-Query**

- $\blacksquare$  A gets the long-term secrets (*pw*) and the internal state
- A takes the entire control on the player and plays on its behalf

Corruptions can occur **before the execution**: Static Corruptions Corruptions can occur **at any moment**: Adaptive Corruptions

CNRS/ENS/PSL/INRIA

David Pointcheval

31/41

# **PAKE Ideal Functionality**

[Canetti-Halevi-Katz-Lindell-MacKenzie – Eurocrypt '05]

### Session Key

- No corrupted players, same passwords
   ⇒ same key, randomly chosen
- No corrupted players, different passwords independent keys, randomly chosen
- A corrupted player
   key chosen by the adversary
- Correct password guess (TestPwd-query)
   key chosen by the adversary
- Incorrect password guess (TestPwd-query) ⇒ independent keys, randomly chosen

CNRS/ENS/PSL/INRIA

David Pointcheval

32/41

### **PAKE Ideal Functionality**

### **Properties**

- The TestPwd-query models the on-line dictionary attacks
- The Corruption-query includes forward secrecy

### Advantages wrt Game-based Security

- No assumption on the distribution of passwords (chosen by the environment)
- Passwords can be related (it models mistyping)
- Security under arbitrary compositions secure channels

# Game-based Security vs. Universal Composability

### **Game-based Security**

In the reduction, the simulator has to emulate the protocol execution **only** up to an evidence the adversary has won ( $pw \implies$  not negl.)

In the global system, the simulation fails when the adversary breaks one sub-protocol whereas other parts could provide protection ( $pw \implies weak \text{ proof!}$ )

### **UC Security**

Simulation handles compositions, but proofs are more complex: the simulator must have an indistinguishable behavior, even when the adversary wins!

In the case of password-based cryptography: the adversary can win with non-negligible probability!

CNRS/ENS/PSL/INRIA	David Pointcheval	35/41
Properties of the NewK Session Key: NewKey-Query		

- A corrupted player ⇒ key chosen by the adversary
- Correct password guess ⇒ key chosen by the adversary

The NewKey-query models possible Key Distribution:

 $\Longrightarrow$  the session key can be controlled by one of the players

The contributiveness property models Key Agreement [Adalla-Catalano-Chevalier-P. – CT-RSA '09]  $\implies$  no player can decide on the key

. . .

# Properties of the TestPwd-Query

### Dictionary Attack: TestPwd-Query

- Correct password guess ⇒ key chosen by the adversary
- Incorrect password guess ⇒ random key

And adversary informed of correct/incorrect guess

The TestPwd-query models Explicit Authentication:

 $\implies$  the players are informed of success/failure

Implicit-Only PAKE models Implicit Authentication [Dupont-Hesse-P.-Reyzin-Yakoubov – Eurocrypt '18]  $\implies$  the keys have to be used to test success/failure

Conclusion

EKE is a secure PAKE in the ROM+ICM:

- BPR secure
- UC secure
- Withstands adaptive corruptions
- Provides forward secrecy
- Can guarantee Explicit or Implicit-Only authentication

All the constructions in the standard model exploit SPHFs:

based on the KOY protocol [Katz-Ostrovsky-Yung – Crypto '01]
 extend the GL protocol [Gennaro-Lindell – Eurocrypt '03]

Let us see SPHF-based PAKE Protocols
