Problem  
statement

The model

Uniformization

Event model

Application

Consider some continuous-time, discrete-event, infinite-horizon control problem.

The standard way to analyze such problems is to reduce them to a discrete-time problem using some **embedding** of a discrete-time process into the continuous-time one.

The optimal policy is deduced from the solution of the discrete-time problem.

# Problem statement (ctd)

Reduction of

time control  
to  
discrete-time  
control

A. Jean-Marie

Problem  
statement

The model

Uniformization

Event model

Application

There are various ways to place the observation points:

- jump instants,
- controllable event instants,
- uniformization instants.

They may result in different **value functions**.

## Question

Is there a way to “play” with the embedding process in order to obtain structural properties of the optimal policy?

# A basic continuous-time control model

As a starting point, consider:

- a continuous-time, **piecewise-constant** process  $\{X(t); t \geq 0\}$  over some discrete state space  $\mathcal{X}$ ;
- a sequence of decision instants  $\{T_n; n \in N\}$ , endogenous
- a finite set of actions  $\mathcal{A}$ ;
- at a decision point  $t$ , given the current state  $x = X(t)$ , there is a feasible set of actions  $\mathcal{A}_x \subset \mathcal{A}$ .

Assuming that action  $a \in \mathcal{A}_s$  is applied,

- a reward  $r(x, a, y)$  is obtained;
  - the state jumps to a random  $T_a(x)$  with distribution  $P_{xay} = \mathbb{P}(T_a(x) = y)$ ;
  - given  $y$ , the next decision point is at  $t + \tau$ , where  $\tau$  has an exponential distribution with parameter  $\lambda_y$ .
- between decision points, a reward is accumulated at  $\ell(x(t))$ , piecewise constant by assumption.

# Basic model (ctd.)

Reduction of  
continuous-  
time control  
to  
discrete-time  
control

A. Jean-Marie

Problem  
statement

The model

Uniformization

Event model

Application

Reward criterion: expected total discounted reward. Given  $X(0) = x$ ,

$$J(x) = \mathbb{E} \left\{ \int_0^{\infty} e^{-\alpha t} \ell(X(t)) dt + \sum_{n=1}^{\infty} e^{-\alpha T_n} r(X(T_n^-), A(T_n), X(T_n^+)) \right\}.$$

The goal is to find the optimal feedback control  $d : \mathcal{X} \rightarrow \mathcal{A}$  (with the constraint that  $d(x) \in \mathcal{A}_x$  for all  $x$ ) to maximize  $J$ .

# Basic embedding

Reduction of  
continuous-  
time control  
to  
discrete-time  
control

A. Jean-Marie

Problem  
statement

The model

Uniformization

Event model

Application

Features of this model:

- control is instantaneous and localized in time
- evolution is strictly Markovian
- immediate generalization to semi-Markov decision/transition instants.

Two possibilities for the observation of the process:

- just before a transition/control:  $\rightarrow V^-(x)$
- just after a transition/control:  $\rightarrow V^+(x)$

Question:

What is their relation with  $J(x)$ ?

# Direct Bellman equations

Reduction of

time control  
to  
discrete-time  
control

A. Jean-Marie

Problem  
statement

The model

Uniformization

Event model

Application

Conditioning on  $T_1$ , the first decision point, we get:

$$V^+(x) = \frac{1}{\alpha + \lambda_x} [\ell(x) + \lambda_x V^-(x)]$$

$$\begin{aligned} V^-(x) &= \max_{a \in \mathcal{A}_x} \left\{ \sum_y P_{xay} (r(x, a, y) + V^+(y)) \right\} \\ &= \max_{a \in \mathcal{A}_x} \left\{ \mathbb{E} (r(x, a, T_a(x)) + V^+(T_a(x))) \right\} . \end{aligned}$$

# Basic functional equations

Eliminating  $V^+$  or  $V^-$  leads to two forms of Bellman's equation:

## Bellman Equations

$$V^+(x) = \frac{1}{\alpha + \lambda_x} \left[ \ell(x) + \lambda_x \max_{a \in \mathcal{A}_x} \sum_y P_{xay} [r(x, a, y) + V^+(y)] \right]$$
$$V^-(x) = \max_{a \in \mathcal{A}_x} \sum_y P_{xay} \left[ r(x, a, y) + \frac{1}{\alpha + \lambda_y} [\ell(y) + \lambda_y V^-(y)] \right].$$

# Uniformization à la carte

For each state  $x$ , define  $\nu_x \geq \lambda_x$  and introduce a new, **uncontrollable** transition point after  $\tau \sim \text{Exp}(\nu_x)$ .

Extend the state space to  $\mathcal{X} \times \{r, u\}$ ,

$r$  = regular event,  $u$  = uniformization event.

Table of rewards and transition probabilities:

$x'$	$a$	$y'$	$r(x', a, y')$	$P_{x'ay'}$
$(x, r)$	$a$	$(y, r)$	$r(x, a, y)$	$\frac{\lambda_y}{\nu_y} P_{xay}$
$(x, r)$	$a$	$(y, u)$	$r(x, a, y)$	$\frac{\nu_y - \lambda_y}{\nu_y} P_{xay}$
$(x, u)$	*	$(x, r)$	0	$\frac{\lambda_y}{\nu_y}$
$(x, u)$	*	$(y, u)$	0	$\frac{\nu_y - \lambda_y}{\nu_y}$

Running reward:  $\ell(x, e) = \ell(x)$ ; transition rate:  $\lambda(x, e) = \nu_x$ .

## Lemma

Let  $V(\cdot)$  be the direct value function and  $V_u(\cdot, \cdot)$  be the uniformized value function. Then:

$$V_u^-(x, r) = V^-(x)$$

$$V_u^-(x, u) = V^+(x)$$

$$V_u^+(x, r) = \frac{1}{\alpha + \nu_x} (\ell(x) + \nu_x V^-(x))$$

$$V_u^+(x, u) = \frac{1}{\alpha + \nu_x} (\ell(x) + \nu_x V^+(x)) .$$

# Interpretations

Reduction of continuous-time control to discrete-time control

A. Jean-Marie

Problem statement

The model

Uniformization

Event model

Application

*No uniformization* ( $\lambda_x = \mu_x$ ):

$$V_u^+(x, r) = \frac{1}{\alpha + \lambda_x} (\ell(x) + \lambda_x V^-(x)) = V^+(x)$$

$$V_u^+(x, u) = \mathbb{E} \left\{ \int_0^{T_1} e^{-\alpha u} \ell(x) du + e^{-\alpha T_1} V^+(x) \right\} .$$

*Hyper-frequent uniformization* ( $\nu_x \rightarrow \infty$ ):

$$\lim_{\nu_x \rightarrow \infty} V_u^+(x, r) = V^-(x) = V_u^-(x, u)$$

$$\lim_{\nu_x \rightarrow \infty} V_u^+(x, u) = V^+(x) = V_u^-(x, r) .$$

*No discounting* ( $\alpha \rightarrow 0$ ):

$$V_u^+(x, r) \sim \frac{\ell(x)}{\nu_x} + V^-(x)$$

$$V_u^+(x, u) \sim \frac{\ell(x)}{\nu_x} + V^+(x) .$$

# Bellman equations for the uniformized process

## Lemma

*The basic value functions  $V^+$  and  $V^-$  satisfy:*

$$V^+(x) = \frac{1}{\alpha + \nu_x} \left[ \ell(x) + (\nu_x - \lambda_x) V^+(x) + \lambda_x \max_{a \in \mathcal{A}_x} \sum_y P_{xay} [r(x, a, y) + V^+(y)] \right]$$

$$V^-(x) = \frac{1}{\alpha + \nu_x} \left[ (\nu_x - \lambda_x) V^-(x) + (\alpha + \lambda_x) \max_{a \in \mathcal{A}_x} \sum_y P_{xay} [r(x, a, y) + \frac{1}{\alpha + \lambda_y} (\ell(y) + \lambda_y V^-(y))] \right]$$

# The event model

If transitions have several “types”, the strictly markovian model requires to extend the state space:  $x = (s, e)$  with  $s$  the actual system state, and  $e$  the event type. We get:

$$V^+(s, e) = \frac{1}{\alpha + \lambda_{s,e}} \left[ \ell(s, e) + \lambda_{s,e} \max_{a \in \mathcal{A}_{s,e}} \sum_{s'} \sum_{e'} P((s, e); a; (s', e')) \left\{ r((s, e), a, (s', e')) + V^+(s', e') \right\} \right]$$
$$V^-(s, e) = \max_{a \in \mathcal{A}_{s,e}} \sum_{s'} \sum_{e'} P((s, e); a; (s', e')) \left[ r((s, e), a, (s', e')) + \frac{\ell(s', e') + \lambda_{s',e'} V^-(s', e')}{\alpha + \lambda_{s',e'}} \right]$$

## Question

Under which conditions is it possible to “get rid” of the event part in the state representation.

Is it possible that:

$$V^+(s, e) = V^+(s) \quad \forall e?$$

# Application: arrival control in the $M/M/1$

Let  $\lambda$  and  $\mu$  denote the arrival and service rates. Reward  $R$  for each accepted customer, and (negative) running reward  $\ell(s)$  for keeping  $s$  customers in queue.

Markovian state:  $x \in \mathbb{N} \times \{a, d\}$  (numbered 1/0 in Puterman). The equations for the value function, after uniformization at uniform rate  $\lambda + \mu$ , are:

$$V_P(s, d)$$

$$= \frac{1}{\alpha + \lambda + \mu} [\ell(s) + \mu V_P((s-1)^+, d) + \lambda V_P(s, a)]$$

$$V_P(s, a)$$

$$= \max \left\{ R + \frac{1}{\alpha + \lambda + \mu} [\ell(s+1) + \mu V_P(s, d) + \lambda V_P(s+1, a)], \frac{1}{\alpha + \lambda + \mu} [\ell(s) + \mu V_P(s-1, d) + \lambda V_P(s, a)] \right\}.$$

Problem  
statement

The model

Uniformization

Event model

Application

But Puterman p. 568 says:

*The system is in state  $\langle s, 0 \rangle$  if there are  $s$  jobs in the system and no arrivals. We observe this state when a transition corresponds to a departure. [...]*

*The state  $\langle s, 1 \rangle$  occurs when there are  $s$  jobs in the system and a new job arrives.*

In our notation, this would correspond to setting:

$$V_P(s, d) = V_u^+((s + 1, d), r)$$

$$V_P(s, a) = V_u^-((s, a), r) .$$
