Supervised learning and regularization

- Data: $x_i \in \mathcal{X}$, $y_i \in \mathcal{Y}$, $i = 1, \ldots, n$

- Minimize with respect to function $f : \mathcal{X} \to \mathcal{Y}$:

$$\sum_{i=1}^{n} \ell(y_i, f(x_i)) \qquad + \qquad \frac{\lambda}{2}\|f\|^2$$

Error on data $\quad + \quad$ Regularization

Loss & function space ? $\qquad$ Norm ?

- Two theoretical/algorithmic issues:

1. Loss
2. **Function space / norm**

Regularizations

- **Main goal: avoid overfitting**

- **Two main lines of work**:

  1. Euclidean and Hilbertian norms (i.e., ℓ_2-norms)
     - Possibility of non linear predictors
     - Non parametric supervised learning and kernel methods
     - Well developped theory and algorithms (see, e.g., Wahba, 1990; Schölkopf and Smola, 2001; Shawe-Taylor and Cristianini, 2004)

Regularizations

- **Main goal: avoid overfitting**

- **Two main lines of work**:

  1. Euclidean and Hilbertian norms (i.e., ℓ_2-norms)
     - Possibility of non linear predictors
     - Non parametric supervised learning and kernel methods
     - Well developped theory and algorithms (see, e.g., Wahba, 1990; Schölkopf and Smola, 2001; Shawe-Taylor and Cristianini, 2004)
  2. Sparsity-inducing norms
     - Usually restricted to linear predictors on vectors $f(x) = w^\top x$
     - Main example: ℓ_1-norm $\|w\|_1 = \sum_{i=1}^{p} |w_i|$
     - Perform model selection as well as regularization
     - **Theory and algorithms "in the making"**

ℓ_2 vs. ℓ_1 - Gaussian hare vs. Laplacian tortoise

- First-order methods (Fu, 1998; Wu and Lange, 2008)
- Homotopy methods (Markowitz, 1956; Efron et al., 2004)

Lasso - Two main recent theoretical results

1. **Support recovery condition** (Zhao and Yu, 2006; Wainwright, 2009; Zou, 2006; Yuan and Lin, 2007): the Lasso is sign-consistent if and only if
$$\|\mathbf{Q}_{\mathbf{J}^c\mathbf{J}}\mathbf{Q}_{\mathbf{JJ}}^{-1}\mathrm{sign}(\mathbf{w_J})\|_\infty \leqslant 1,$$
where $\mathbf{Q} = \lim_{n\to+\infty} \frac{1}{n}\sum_{i=1}^n x_i x_i^\top \in \mathbb{R}^{p\times p}$ and $\mathbf{J} = \mathrm{Supp}(\mathbf{w})$

Lasso - Two main recent theoretical results

1. **Support recovery condition** (Zhao and Yu, 2006; Wainwright, 2009; Zou, 2006; Yuan and Lin, 2007): the Lasso is sign-consistent if and only if
$$\|\mathbf{Q_{J^c J}} \mathbf{Q_{JJ}^{-1}} \operatorname{sign}(\mathbf{w_J})\|_\infty \leqslant 1,$$
where $\mathbf{Q} = \lim_{n \to +\infty} \frac{1}{n} \sum_{i=1}^{n} x_i x_i^\top \in \mathbb{R}^{p \times p}$ and $\mathbf{J} = \operatorname{Supp}(\mathbf{w})$

2. **Exponentially many irrelevant variables** (Zhao and Yu, 2006; Wainwright, 2009; Bickel et al., 2009; Lounici, 2008; Meinshausen and Yu, 2008): under appropriate assumptions, consistency is possible as long as
$$\log p = O(n)$$

Going beyond the Lasso

- ℓ_1-norm for **linear** feature selection in **high dimensions**

  - Lasso usually not applicable directly

- **Non-linearities**

- **Dealing with exponentially many features**

- **Sparse learning on matrices**

Going beyond the Lasso
Non-linearity - Multiple kernel learning

- **Multiple kernel learning**

  - Learn sparse combination of matrices $k(x, x') = \sum_{j=1}^{p} \eta_j k_j(x, x')$
  - Mixing positive aspects of ℓ_1-norms and ℓ_2-norms

- **Equivalent to group Lasso**

  - p multi-dimensional features $\Phi_j(x)$, where

  $$k_j(x, x') = \Phi_j(x)^\top \Phi_j(x')$$

  - learn predictor $\sum_{j=1}^{p} w_j^\top \Phi_j(x)$
  - Penalization by $\sum_{j=1}^{p} \|w_j\|_2$

Going beyond the Lasso
Structured set of features

- **Dealing with exponentially many features**

  – Can we design efficient algorithms for the case $\log p \approx n$?
  – Use structure to reduce the number of allowed patterns of zeros
  – Recursivity, **hierarchies** and factorization

- **Prior information on sparsity patterns**

  – Grouped variables with overlapping groups

Going beyond the Lasso
Sparse methods on matrices

- **Learning problems on matrices**

  – Multi-task learning
  – Multi-category classification
  – Matrix completion
  – Image denoising
  – NMF, topic models, etc.

- **Matrix factorization**

 – Two types of sparsity (low-rank or dictionary learning)

Sparse methods for machine learning
Outline

- **Introduction - Overview**

- **Sparse linear estimation with the ℓ_1-norm**

  - Convex optimization and algorithms
  - Theoretical results

- **Structured sparse methods on vectors**

  - Groups of features / Multiple kernel learning
  - Extensions (hierarchical or overlapping groups)

- **Sparse methods on matrices**

  - Multi-task learning
  - Matrix factorization (low-rank, sparse PCA, dictionary learning)

Why ℓ_1-norm constraints leads to sparsity?

- Example: minimize quadratic function $Q(w)$ subject to $\|w\|_1 \leqslant T$.

  – coupled soft thresholding

- Geometric interpretation

  – NB : penalizing is "equivalent" to constraining
ℓ_1-norm regularization (linear setting)

- Data: covariates $x_i \in \mathbb{R}^p$, responses $y_i \in \mathcal{Y}$, $i = 1, \ldots, n$

- Minimize with respect to loadings/weights $w \in \mathbb{R}^p$:

$$J(w) = \sum_{i=1}^{n} \ell(y_i, w^\top x_i) \quad + \quad \lambda \|w\|_1$$

$$\text{Error on data} \quad + \quad \text{Regularization}$$

- Including a constant term b? Penalizing or constraining?

- square loss $\Rightarrow$ basis pursuit in signal processing (Chen et al., 2001), Lasso in statistics/machine learning (Tibshirani, 1996)

A review of nonsmooth convex analysis and optimization

- **Analysis:** optimality conditions

- **Optimization:** algorithms

  – First-order methods

- **Books**: Boyd and Vandenberghe (2004), Bonnans et al. (2003), Bertsekas (1995), Borwein and Lewis (2000)

Optimality conditions for smooth optimization
Zero gradient

- Example: ℓ_2-regularization: $\displaystyle\min_{w\in\mathbb{R}^p}\sum_{i=1}^{n}\ell(y_i,w^\top x_i)+\frac{\lambda}{2}\|w\|_2^2$

  – Gradient $\nabla J(w)=\sum_{i=1}^{n}\ell'(y_i,w^\top x_i)x_i+\lambda w$ where $\ell'(y_i,w^\top x_i)$
    is the partial derivative of the loss w.r.t the second variable

  – If square loss, $\sum_{i=1}^{n}\ell(y_i,w^\top x_i)=\frac{1}{2}\|y-Xw\|_2^2$
    * gradient $=-X^\top(y-Xw)+\lambda w$
    * normal equations $\Rightarrow w=(X^\top X+\lambda I)^{-1}X^\top y$

# Optimality conditions for smooth optimization
Zero gradient

- Example: ℓ_2-regularization: $\min_{w \in \mathbb{R}^p} \sum_{i=1}^{n} \ell(y_i, w^\top x_i) + \frac{\lambda}{2}\|w\|_2^2$

  - Gradient $\nabla J(w) = \sum_{i=1}^{n} \ell'(y_i, w^\top x_i)x_i + \lambda w$ where $\ell'(y_i, w^\top x_i)$ is the partial derivative of the loss w.r.t the second variable
  - If square loss, $\sum_{i=1}^{n} \ell(y_i, w^\top x_i) = \frac{1}{2}\|y - Xw\|_2^2$
    * gradient $= -X^\top(y - Xw) + \lambda w$
    * normal equations $\Rightarrow w = (X^\top X + \lambda I)^{-1}X^\top y$

- ℓ_1-**norm is non differentiable!**

  - cannot compute the gradient of the absolute value

  $\Rightarrow$ **Directional derivatives** (or subgradient)

Directional derivatives - convex functions on $\mathbb{R}^p$

- Directional derivative in the direction Δ at w:

$$\nabla J(w, \Delta) = \lim_{\varepsilon \to 0+} \frac{J(w + \varepsilon\Delta) - J(w)}{\varepsilon}$$

- Always exist when J is convex and continuous

- Main idea: in non smooth situations, may need to look at all directions Δ and not simply p independent ones

- **Proposition**: J is differentiable at w, if and only if $\Delta \mapsto \nabla J(w, \Delta)$ is linear. Then, $\nabla J(w, \Delta) = \nabla J(w)^\top \Delta$

Optimality conditions for convex functions

- Unconstrained minimization (function defined on $\mathbb{R}^p$):

  - **Proposition**: w is optimal **if and only if** $\forall \Delta \in \mathbb{R}^p$, $\nabla J(w, \Delta) \geqslant 0$
  - Go up locally in all directions

- Reduces to zero-gradient for smooth problems

- Constrained minimization (function defined on a convex set K)

  - restrict Δ to directions so that $w + \varepsilon \Delta \in K$ for small ε

Directional derivatives for ℓ_1-norm regularization

- Function $J(w) = \sum_{i=1}^{n} \ell(y_i, w^\top x_i) + \lambda\|w\|_1 = L(w) + \lambda\|w\|_1$

- ℓ_1-norm: $\|w + \varepsilon\Delta\|_1 - \|w\|_1 = \sum_{j,\ w_j \neq 0} \{|w_j + \varepsilon\Delta_j| - |w_j|\} + \sum_{j,\ w_j = 0} |\varepsilon\Delta_j|$

- Thus,

$$\nabla J(w, \Delta) = \nabla L(w)^\top \Delta + \lambda \sum_{j,\ w_j \neq 0} \mathrm{sign}(w_j)\Delta_j + \lambda \sum_{j,\ w_j = 0} |\Delta_j|$$

$$= \sum_{j,\ w_j \neq 0} [\nabla L(w)_j + \lambda\,\mathrm{sign}(w_j)]\Delta_j + \sum_{j,\ w_j = 0} [\nabla L(w)_j \Delta_j + \lambda|\Delta_j|]$$

- Separability of optimality conditions

Optimality conditions for ℓ_1-norm regularization

- **General loss:** w optimal if and only if for all $j \in \{1, \ldots, p\}$,

$$\mathrm{sign}(w_j) \neq 0 \quad \Rightarrow \quad \nabla L(w)_j + \lambda \, \mathrm{sign}(w_j) = 0$$

$$\mathrm{sign}(w_j) = 0 \quad \Rightarrow \quad |\nabla L(w)_j| \leqslant \lambda$$

- **Square loss:** w optimal if and only if for all $j \in \{1, \ldots, p\}$,

$$\mathrm{sign}(w_j) \neq 0 \quad \Rightarrow \quad -X_j^\top (y - Xw) + \lambda \, \mathrm{sign}(w_j) = 0$$

$$\mathrm{sign}(w_j) = 0 \quad \Rightarrow \quad |X_j^\top (y - Xw)| \leqslant \lambda$$

  - For $J \subset \{1, \ldots, p\}$, $X_J \in \mathbb{R}^{n \times |J|} = X(:, J)$ denotes the columns of X indexed by J, i.e., variables indexed by J

First order methods for convex optimization on $\mathbb{R}^p$
Smooth optimization

- **Gradient descent**: $w_{t+1} = w_t - \alpha_t \nabla J(w_t)$

  - with line search: search for a decent (not necessarily best) α_t
  - fixed diminishing step size, e.g., $\alpha_t = a(t+b)^{-1}$

- Convergence of $f(w_t)$ to $f^* = \min_{w \in \mathbb{R}^p} f(w)$ (Nesterov, 2003)

  - f convex and M-Lipschitz: $\qquad\qquad\qquad f(w_t) - f^* = O\big(M/\sqrt{t}\big)$
  - and, differentiable with L-Lipschitz gradient: $f(w_t) - f^* = O\big(L/t\big)$
  - and, f μ-strongly convex: $\qquad\qquad f(w_t) - f^* = O\big(L \exp(-4t\tfrac{\mu}{L})\big)$

- $\frac{\mu}{L} =$ condition number of the optimization problem

- Coordinate descent: similar properties

- NB: "optimal scheme" $f(w_t) - f^* = O\big(L \min\{\exp(-4t\sqrt{\mu/L}), t^{-2}\}\big)$

First-order methods for convex optimization on $\mathbb{R}^p$
Non smooth optimization

- First-order methods for non differentiable objective

  - Subgradient descent: $w_{t+1} = w_t - \alpha_t g_t$, with $g_t \in \partial J(w_t)$, i.e., such that $\forall \Delta, g_t^\top \Delta \leqslant \nabla J(w_t, \Delta)$
    * with exact line search: not always convergent (see counter-example)
    * diminishing step size, e.g., $\alpha_t = a(t+b)^{-1}$: convergent
  - Coordinate descent: not always convergent (show counter-example)

- Convergence rates (f convex and M-Lipschitz): $f(w_t) - f^* = O\left(\frac{M}{\sqrt{t}}\right)$

Counter-example
Coordinate descent for nonsmooth objectives
Counter-example (Bertsekas, 1995)
Steepest descent for nonsmooth objectives

- $q(x_1, x_2) = \begin{cases} -5(9x_1^2 + 16x_2^2)^{1/2} & \text{if } x_1 > |x_2| \\ -(9x_1 + 16|x_2|)^{1/2} & \text{if } x_1 \leqslant |x_2| \end{cases}$

- Steepest descent starting from any x such that $x_1 > |x_2| > (9/16)^2 |x_1|$
Regularized problems - Proximal methods

- Gradient descent as a proximal method (differentiable functions)

  - $w_{t+1} = \arg\min_{w \in \mathbb{R}^p} J(w_t) + (w - w_t)^\top \nabla J(w_t) + \dfrac{L}{2}\|w - w_t\|_2^2$
  - $w_{t+1} = w_t - \dfrac{1}{L}\nabla J(w_t)$

- Problems of the form: $\boxed{\min_{w \in \mathbb{R}^p} L(w) + \lambda\Omega(w)}$

  - $w_{t+1} = \arg\min_{w \in \mathbb{R}^p} L(w_t) + (w - w_t)^\top \nabla L(w_t) + \lambda\Omega(w) + \dfrac{L}{2}\|w - w_t\|_2^2$
  - Thresholded gradient descent

- Similar convergence rates than smooth optimization

  - Acceleration methods (Nesterov, 2007; Beck and Teboulle, 2009)
  - **depends on the condition number of the loss**

Cheap (and not dirty) algorithms for all losses

- **Proximal methods**

Cheap (and not dirty) algorithms for all losses

- **Proximal methods**

- **Coordinate descent** (Fu, 1998; Wu and Lange, 2008; Friedman et al., 2007)

  – convergent **here** under reasonable assumptions! (Bertsekas, 1995)
  – separability of optimality conditions
  – equivalent to iterative thresholding

Cheap (and not dirty) algorithms for all losses

- **Proximal methods**

- **Coordinate descent** (Fu, 1998; Wu and Lange, 2008; Friedman et al., 2007)

  - convergent **here** under reasonable assumptions! (Bertsekas, 1995)
  - separability of optimality conditions
  - equivalent to iterative thresholding

- **"η-trick"** (Rakotomamonjy et al., 2008; Jenatton et al., 2009b)

  - Notice that $\sum_{j=1}^{p} |w_j| = \min_{\eta \geqslant 0} \frac{1}{2} \sum_{j=1}^{p} \left\{ \frac{w_j^2}{\eta_j} + \eta_j \right\}$
  - Alternating minimization with respect to η (closed-form) and w (weighted squared ℓ_2-norm regularized problem)

Cheap (and not dirty) algorithms for all losses

- **Proximal methods**

- **Coordinate descent** (Fu, 1998; Wu and Lange, 2008; Friedman et al., 2007)

  – convergent **here** under reasonable assumptions! (Bertsekas, 1995)
  – separability of optimality conditions
  – equivalent to iterative thresholding

- **"η-trick"** (Rakotomamonjy et al., 2008; Jenatton et al., 2009b)

  – Notice that $\sum_{j=1}^{p} |w_j| = \min_{\eta \geqslant 0} \frac{1}{2} \sum_{j=1}^{p} \left\{ \frac{w_j^2}{\eta_j} + \eta_j \right\}$
  – Alternating minimization with respect to η (closed-form) and w (weighted squared ℓ_2-norm regularized problem)

- **Dedicated algorithms that use sparsity** (active sets/homotopy)

Special case of square loss

- **Quadratic programming formulation**: minimize

$$\frac{1}{2}\|y - Xw\|^2 + \lambda \sum_{j=1}^{p}(w_j^+ + w_j^-) \text{ such that } w = w^+ - w^-, \ w^+ \geqslant 0, \ w^- \geqslant 0$$

Special case of square loss

- **Quadratic programming formulation**: minimize

$$\frac{1}{2}\|y - Xw\|^2 + \lambda \sum_{j=1}^{p} (w_j^+ + w_j^-) \text{ such that } w = w^+ - w^-, \ w^+ \geqslant 0, \ w^- \geqslant 0$$

  - **generic toolboxes $\Rightarrow$ very slow**

- **Main property**: if the sign pattern $s \in \{-1, 0, 1\}^p$ of the solution is known, the solution can be obtained in closed form

  - Lasso equivalent to minimizing $\frac{1}{2}\|y - X_J w_J\|^2 + \lambda s_J^\top w_J$ w.r.t. w_J where $J = \{j, s_j \neq 0\}$.
  - Closed form solution $w_J = (X_J^\top X_J)^{-1}(X_J^\top y - \lambda s_J)$

- **Algorithm: "Guess" s and check optimality conditions**

Optimality conditions for the sign vector s (Lasso)

- For $s \in \{-1, 0, 1\}^p$ sign vector, $J = \{j, s_j \neq 0\}$ the nonzero pattern

- potential closed form solution: $w_J = (X_J^\top X_J)^{-1}(X_J^\top y - \lambda s_J)$ and $w_{J^c} = 0$

- s is optimal if and only if

  - active variables: $\quad \mathrm{sign}(w_J) = s_J$
  - inactive variables: $\|X_{J^c}^\top(y - X_J w_J)\|_\infty \leqslant \lambda$

- **Active set algorithms** (Lee et al., 2007; Roth and Fischer, 2008)

  - Construct J iteratively by adding variables to the active set
  - Only requires to invert small linear systems

Homotopy methods for the square loss (Markowitz, 1956; Osborne et al., 2000; Efron et al., 2004)

- **Goal**: Get all solutions for all possible values of the regularization parameter λ

- Same idea as before: if the sign vector is known,

$$w_J^*(\lambda) = (X_J^\top X_J)^{-1}(X_J^\top y - \lambda s_J)$$

  valid, as long as,

  − sign condition: $\qquad \operatorname{sign}(w_J^*(\lambda)) = s_J$
  − subgradient condition: $\|X_{J^c}^\top(X_J w_J^*(\lambda) - y)\|_\infty \leqslant \lambda$
  − this defines an interval on λ: the path is thus **piecewise affine**

- Simply need to find break points and directions

Piecewise linear paths

Algorithms for ℓ_1-norms (square loss): Gaussian hare vs. Laplacian tortoise

- Coordinate descent: $O(pn)$ per iterations for ℓ_1 and ℓ_2

- "Exact" algorithms: $O(kpn)$ for ℓ_1 **vs.** $O(p^2n)$ for ℓ_2

Additional methods - Softwares

- Many contributions in signal processing, optimization, machine learning

  – Extensions to stochastic setting (Bottou and Bousquet, 2008)

- Extensions to other sparsity-inducing norms

  – Computing proximal operator

- **Softwares**

  – Many available codes
  – SPAMS (SPArse Modeling Software) - note difference with SpAM (Ravikumar et al., 2008)
    `http://www.di.ens.fr/willow/SPAMS/`

Sparse methods for machine learning
Outline

- **Introduction - Overview**

- **Sparse linear estimation with the ℓ_1-norm**

  - Convex optimization and algorithms
  - Theoretical results

- **Structured sparse methods on vectors**

  - Groups of features / Multiple kernel learning
  - Extensions (hierarchical or overlapping groups)

- **Sparse methods on matrices**

  - Multi-task learning
  - Matrix factorization (low-rank, sparse PCA, dictionary learning)

Theoretical results - Square loss

- Main assumption: data generated from a certain sparse $\mathbf{w}$

- Three main problems:

  1. **Regular consistency**: convergence of estimator $\hat{w}$ to $\mathbf{w}$, i.e., $\|\hat{w} - \mathbf{w}\|$ tends to zero when n tends to ∞
  2. **Model selection consistency**: convergence of the sparsity pattern of $\hat{w}$ to the pattern $\mathbf{w}$
  3. **Efficiency**: convergence of predictions with $\hat{w}$ to the predictions with $\mathbf{w}$, i.e., $\frac{1}{n}\|X\hat{w} - X\mathbf{w}\|_2^2$ tends to zero

- Main results:

  - **Condition for model consistency (support recovery)**
  - **High-dimensional inference**

Model selection consistency (Lasso)

- Assume $\mathbf{w}$ sparse and denote $\mathbf{J} = \{j, \mathbf{w}_j \neq 0\}$ the nonzero pattern

- **Support recovery condition** (Zhao and Yu, 2006; Wainwright, 2009; Zou, 2006; Yuan and Lin, 2007): the Lasso is sign-consistent if and only if
$$\boxed{\|\mathbf{Q}_{\mathbf{J}^c\mathbf{J}}\mathbf{Q}_{\mathbf{J}\mathbf{J}}^{-1}\mathrm{sign}(\mathbf{w}_{\mathbf{J}})\|_\infty \leqslant 1}$$
where $\mathbf{Q} = \lim_{n \to +\infty} \frac{1}{n}\sum_{i=1}^n x_i x_i^\top \in \mathbb{R}^{p \times p}$ and $\mathbf{J} = \mathrm{Supp}(\mathbf{w})$

Model selection consistency (Lasso)

- Assume $\mathbf{w}$ sparse and denote $\mathbf{J} = \{j, \mathbf{w}_j \neq 0\}$ the nonzero pattern

- **Support recovery condition** (Zhao and Yu, 2006; Wainwright, 2009; Zou, 2006; Yuan and Lin, 2007): the Lasso is sign-consistent if and only if
$$\boxed{\|\mathbf{Q}_{\mathbf{J}^c\mathbf{J}}\mathbf{Q}_{\mathbf{J}\mathbf{J}}^{-1}\mathrm{sign}(\mathbf{w}_{\mathbf{J}})\|_\infty \leqslant 1}$$
where $\mathbf{Q} = \lim_{n\to+\infty} \frac{1}{n}\sum_{i=1}^n x_i x_i^\top \in \mathbb{R}^{p\times p}$ and $\mathbf{J} = \mathrm{Supp}(\mathbf{w})$

- Condition depends on $\mathbf{w}$ and $\mathbf{J}$ (may be relaxed)

  - may be relaxed by maximizing out $\mathrm{sign}(\mathbf{w})$ or $\mathbf{J}$

- Valid in low and high-dimensional settings

- Requires lower-bound on magnitude of nonzero $\mathbf{w}_j$

Model selection consistency (Lasso)

- Assume $\mathbf{w}$ sparse and denote $\mathbf{J} = \{j, \mathbf{w}_j \neq 0\}$ the nonzero pattern

- **Support recovery condition** (Zhao and Yu, 2006; Wainwright, 2009; Zou, 2006; Yuan and Lin, 2007): the Lasso is sign-consistent if and only if

$$\boxed{\|\mathbf{Q}_{\mathbf{J}^c\mathbf{J}}\mathbf{Q}_{\mathbf{J}\mathbf{J}}^{-1}\mathrm{sign}(\mathbf{w}_{\mathbf{J}})\|_\infty \leqslant 1}$$

  where $\mathbf{Q} = \lim_{n \to +\infty} \frac{1}{n}\sum_{i=1}^n x_i x_i^\top \in \mathbb{R}^{p\times p}$ and $\mathbf{J} = \mathrm{Supp}(\mathbf{w})$

- **The Lasso is usually not model-consistent**

  - Selects more variables than necessary (see, e.g., Lv and Fan, 2009)
  - **Fixing the Lasso**: adaptive Lasso (Zou, 2006), relaxed Lasso (Meinshausen, 2008), thresholding (Lounici, 2008), Bolasso (Bach, 2008a), stability selection (Meinshausen and Bühlmann, 2008), Wasserman and Roeder (2009)

Adaptive Lasso and concave penalization

- **Adaptive Lasso** (Zou, 2006; Huang et al., 2008)

  - Weighted ℓ_1-norm: $\displaystyle\min_{w\in\mathbb{R}^p} L(w) + \lambda\sum_{j=1}^{p} \frac{|w_j|}{|\hat{w}_j|^\alpha}$
  - $\hat{w}$ estimator obtained from ℓ_2 or ℓ_1 regularization

- **Reformulation in terms of concave penalization**

$$\min_{w\in\mathbb{R}^p} L(w) + \sum_{j=1}^{p} g(|w_j|)$$
  - Example: $g(|w_j|) = |w_j|^{1/2}$ or $\log|w_j|$. Closer to the ℓ_0 penalty
  - Concave-convex procedure: replace $g(|w_j|)$ by affine upper bound
  - Better sparsity-inducing properties (Fan and Li, 2001; Zou and Li, 2008; Zhang, 2008b)

Bolasso (Bach, 2008a)

- **Property**: for a specific choice of regularization parameter $\lambda \approx \sqrt{n}$:

  - all variables in $\mathbf{J}$ are always selected with high probability
  - all other ones selected with probability in $(0, 1)$

- Use the bootstrap to simulate several replications

  - Intersecting supports of variables
  - Final estimation of w on the entire dataset

Model selection consistency of the Lasso/Bolasso

• probabilities of selection of each variable vs. regularization param. μ
LASSO

BOLASSO
Support recovery condition   satisfied   not satisfied

High-dimensional inference
Going beyond exact support recovery

- Theoretical results usually assume that non-zero $\mathbf{w}_j$ are large enough, i.e., $|\mathbf{w}_j| \geqslant \sigma \sqrt{\frac{\log p}{n}}$

- **May include too many variables but still predict well**

- Oracle inequalities

  – Predict as well as the estimator obtained with the knowledge of $\mathbf{J}$
  – Assume i.i.d. Gaussian noise with variance σ^2
  – We have:
  $$\frac{1}{n}\mathbb{E}\|X\hat{w}_{\text{oracle}} - X\mathbf{w}\|_2^2 = \frac{\sigma^2|J|}{n}$$

High-dimensional inference
Variable selection without computational limits

- Approaches based on penalized criteria (close to BIC)

$$\min_{J \subset \{1,\ldots,p\}} \Big\{ \min_{w_J \in \mathbb{R}^{|J|}} \|y - X_J w_J\|_2^2 \Big\} + C\sigma^2 |J| \Big(1 + \log \frac{p}{|J|}\Big)$$

- **Oracle inequality** if data generated by $\mathbf{w}$ with k non-zeros (Massart, 2003; Bunea et al., 2007):

$$\frac{1}{n}\|X\hat{w} - X\mathbf{w}\|_2^2 \leqslant C\frac{k\sigma^2}{n}\Big(1 + \log \frac{p}{k}\Big)$$

- Gaussian noise - **No assumptions regarding correlations**

- **Scaling between dimensions**: $\frac{k \log p}{n}$ small

- Optimal in the minimax sense

Where does the $\log p$ come from?

- Expectation of the maximum of p Gaussian variables $\approx \sqrt{\log p}$

- Union-bound:

$$
\begin{aligned}
\mathbb{P}(\exists j \in \mathbf{J}^c, |X_j^\top \varepsilon| \geqslant \lambda) \quad &\leqslant \quad \sum_{j \in \mathbf{J}^c} \mathbb{P}(|X_j^\top \varepsilon| \geqslant \lambda) \\
&\leqslant \quad |\mathbf{J}^c| e^{-\frac{\lambda^2}{2n\sigma^2}} \leqslant p e^{-\frac{A^2}{2} \log p} = p^{1-\frac{A^2}{2}}
\end{aligned}
$$

High-dimensional inference (Lasso)

- **Main result**: we only need $k \log p = O(n)$

  - if $\mathbf{w}$ is sufficiently sparse
  - **and** input variables are not too correlated

- Precise conditions on covariance matrix $\mathbf{Q} = \frac{1}{n} X^\top X$.

  - **Mutual incoherence** (Lounici, 2008)
  - **Restricted eigenvalue conditions** (Bickel et al., 2009)
  - Sparse eigenvalues (Meinshausen and Yu, 2008)
  - Null space property (Donoho and Tanner, 2005)

- Links with signal processing and compressed sensing (Candès and Wakin, 2008)

- Assume that $\mathbf{Q}$ has unit diagonal

Mutual incoherence (uniform low correlations)

- **Theorem** (Lounici, 2008):

  - $y_i = \mathbf{w}^\top x_i + \varepsilon_i$, ε i.i.d. normal with mean zero and variance σ^2
  - $\mathbf{Q} = X^\top X / n$ with unit diagonal and cross-terms less than $\dfrac{1}{14k}$
  - if $\|\mathbf{w}\|_0 \leqslant k$, and $A^2 > 8$, then, with $\lambda = A\sigma\sqrt{n \log p}$

$$
\mathbb{P}\left(\|\hat{w} - \mathbf{w}\|_\infty \leqslant 5A\sigma \left(\frac{\log p}{n}\right)^{1/2} \right) \geqslant 1 - p^{1 - A^2/8}
$$

- Model consistency by thresholding if $\displaystyle\min_{j, \mathbf{w}_j \neq 0} |\mathbf{w}_j| > C\sigma\sqrt{\dfrac{\log p}{n}}$

- Mutual incoherence condition depends *strongly* on k

- Improved result by averaging over sparsity patterns (Candès and Plan, 2009b)

Where does the $\log p$ come from?

- Expectation of the maximum of p Gaussian variables $\approx \sqrt{\log p}$

- Union-bound:

$$\mathbb{P}(\exists j \in \mathbf{J}^c, |X_j^\top \varepsilon| \geqslant \lambda) \;\leqslant\; \sum_{j \in \mathbf{J}^c} \mathbb{P}(|X_j^\top \varepsilon| \geqslant \lambda)$$

$$\leqslant\; |\mathbf{J}^c| e^{-\frac{\lambda^2}{2n\sigma^2}} \leqslant p e^{-\frac{A^2}{2}\log p} = p^{1-\frac{A^2}{2}}$$

Restricted eigenvalue conditions

- **Theorem** (Bickel et al., 2009):

  - assume

  $$\kappa(k)^2 = \min_{|J| \leqslant k} \min_{\Delta,\ \|\Delta_{J^c}\|_1 \leqslant \|\Delta_J\|_1} \frac{\Delta^\top \mathbf{Q} \Delta}{\|\Delta_J\|_2^2} > 0$$

  - assume $\lambda = A\sigma\sqrt{n \log p}$ and $A^2 > 8$
  - then, with probability $1 - p^{1 - A^2/8}$, we have

  $$\text{estimation error} \qquad \|\hat{w} - \mathbf{w}\|_1 \leqslant \frac{16A}{\kappa^2(k)}\sigma k \sqrt{\frac{\log p}{n}}$$

  $$\text{prediction error} \qquad \frac{1}{n}\|X\hat{w} - X\mathbf{w}\|_2^2 \leqslant \frac{16A^2}{\kappa^2(k)}\frac{\sigma^2 k}{n} \log p$$

- Condition imposes a potentially hidden scaling between (n, p, k)

- Condition always satisfied for $\mathbf{Q} = I$

Checking sufficient conditions

- **Most of the conditions are not computable in polynomial time**

- **Random matrices**

  - Sample $X \in \mathbb{R}^{n \times p}$ from the Gaussian ensemble
  - Conditions satisfied with high probability for certain (n, p, k)
  - Example from Wainwright (2009): $\boxed{n \geqslant Ck \log p}$

- **Checking with convex optimization**

  - Relax conditions to convex optimization problems (d'Aspremont et al., 2008; Juditsky and Nemirovski, 2008; d'Aspremont and El Ghaoui, 2008)
  - Example: sparse eigenvalues $\min_{|J| \leqslant k} \lambda_{\min}(\mathbf{Q}_{JJ})$
  - Open problem: verifiable assumptions still lead to weaker results

Sparse methods
Common extensions

- **Removing bias of the estimator**

  - Keep the active set, and perform unregularized restricted estimation (Candès and Tao, 2007)
  - Better theoretical bounds
  - Potential problems of robustness

- **Elastic net** (Zou and Hastie, 2005)

  - Replace $\lambda \|w\|_1$ by $\lambda \|w\|_1 + \varepsilon \|w\|_2^2$
  - Make the optimization strongly convex with unique solution
  - Better behavior with heavily correlated variables

Relevance of theoretical results

- **Most results only for the square loss**

  – Extend to other losses (Van De Geer, 2008; Bach, 2009b)

- **Most results only for ℓ_1-regularization**

  – May be extended to other norms (see, e.g., Huang and Zhang, 2009; Bach, 2008b)

- **Condition on correlations**

  – very restrictive, far from results for BIC penalty

- **Non sparse generating vector**

  – little work on robustness to lack of sparsity

- **Estimation of regularization parameter**

  – No satisfactory solution $\Rightarrow$ open problem

Alternative sparse methods
Greedy methods

- Forward selection

- Forward-backward selection

- Non-convex method

  – Harder to analyze
  – Simpler to implement
  – Problems of stability

- Positive theoretical results (Zhang, 2009, 2008a)

  – Similar sufficient conditions than for the Lasso

Alternative sparse methods
Bayesian methods

- Lasso: minimize $\sum_{i=1}^{n} (y_i - w^\top x_i)^2 + \lambda \|w\|_1$

  - Equivalent to MAP estimation with Gaussian likelihood and factorized **Laplace** prior $p(w) \propto \prod_{j=1}^{p} e^{-\lambda |w_j|}$ (Seeger, 2008)
  - **However, posterior puts zero weight on exact zeros**

- Heavy-tailed distributions as a proxy to sparsity

  - Student distributions (Caron and Doucet, 2008)
  - Generalized hyperbolic priors (Archambeau and Bach, 2008)
  - Instance of automatic relevance determination (Neal, 1996)

- Mixtures of "Diracs" and another absolutely continuous distributions, e.g., "spike and slab" (Ishwaran and Rao, 2005)

- Less theory than frequentist methods

Comparing Lasso and other strategies for linear regression

- Compared methods to reach the least-square solution

  - Ridge regression: $\min\limits_{w \in \mathbb{R}^p} \dfrac{1}{2}\|y - Xw\|_2^2 + \dfrac{\lambda}{2}\|w\|_2^2$

  - Lasso: $\min\limits_{w \in \mathbb{R}^p} \dfrac{1}{2}\|y - Xw\|_2^2 + \lambda\|w\|_1$

  - Forward greedy:
    * Initialization with empty set
    * Sequentially add the variable that best reduces the square loss

- Each method builds a path of solutions from 0 to ordinary least-squares solution

- Regularization parameters selected on the test set

Simulation results

- i.i.d. Gaussian design matrix, $k = 4$, $n = 64$, $p \in [2, 256]$, SNR $= 1$
- Note stability to non-sparsity and variability
Sparse
Rotated (non sparse)

Summary
ℓ_1-norm regularization

- ℓ_1-norm regularization leads to **nonsmooth optimization problems**

  - analysis through directional derivatives or subgradients
  - optimization may or may not take advantage of sparsity

- ℓ_1-norm regularization allows **high-dimensional inference**

- Interesting problems for ℓ_1-regularization

  - Stable variable selection
  - Weaker sufficient conditions (for weaker results)
  - Estimation of regularization parameter (all bounds depend on the unknown noise variance σ^2)

Extensions

- **Sparse methods are not limited to the square loss**

  – logistic loss: algorithms (Beck and Teboulle, 2009) and theory (Van De Geer, 2008; Bach, 2009b)

- **Sparse methods are not limited to supervised learning**

  – Learning the structure of Gaussian graphical models (Meinshausen and Bühlmann, 2006; Banerjee et al., 2008)
  – Sparsity on matrices (last part of the tutorial)

- **Sparse methods are not limited to variable selection in a linear model**

  – **See next part of the tutorial**

Questions?

Sparse methods for machine learning
Outline

- **Introduction - Overview**

- **Sparse linear estimation with the ℓ_1-norm**

  - Convex optimization and algorithms
  - Theoretical results

- **Structured sparse methods on vectors**

  - Groups of features / Multiple kernel learning
  - Extensions (hierarchical or overlapping groups)

- **Sparse methods on matrices**

  - Multi-task learning
  - Matrix factorization (low-rank, sparse PCA, dictionary learning)

Penalization with grouped variables (Yuan and Lin, 2006)

- Assume that $\{1, \ldots, p\}$ is **partitioned** into m groups $G_1, \ldots, G_m$

- Penalization by $\sum_{i=1}^{m} \|w_{G_i}\|_2$, often called ℓ_1-ℓ_2 norm

- Induces group sparsity

  - Some groups entirely set to zero
  - no zeros within groups

- In this tutorial:

  - Groups may have infinite size $\Rightarrow$ **MKL**
  - Groups may overlap $\Rightarrow$ **structured sparsity**

Linear vs. non-linear methods

- All methods in this tutorial are **linear in the parameters**

- By replacing x by features $\Phi(x)$, they can be made **non linear in the data**

- **Implicit vs. explicit features**

  - ℓ_1-norm: explicit features
  - ℓ_2-norm: representer theorem allows to consider implicit features if their dot products can be computed easily (kernel methods)

Kernel methods: regularization by ℓ_2-norm

- Data: $x_i \in \mathcal{X}$, $y_i \in \mathcal{Y}$, $i = 1, \ldots, n$, with **features** $\Phi(x) \in \mathcal{F} = \mathbb{R}^p$

  – Predictor $f(x) = w^\top \Phi(x)$ linear in the features

- Optimization problem:
$$\min_{w \in \mathbb{R}^p} \sum_{i=1}^{n} \ell(y_i, w^\top \Phi(x_i)) + \frac{\lambda}{2} \|w\|_2^2$$

Kernel methods: regularization by ℓ_2-norm

- Data: $x_i \in \mathcal{X}$, $y_i \in \mathcal{Y}$, $i = 1, \dots, n$, with **features** $\Phi(x) \in \mathcal{F} = \mathbb{R}^p$

  – Predictor $f(x) = w^\top \Phi(x)$ linear in the features

- Optimization problem:
$$\min_{w \in \mathbb{R}^p} \sum_{i=1}^{n} \ell(y_i, w^\top \Phi(x_i)) + \frac{\lambda}{2} \|w\|_2^2$$

- **Representer theorem** (Kimeldorf and Wahba, 1971): solution must be of the form $w = \sum_{i=1}^{n} \alpha_i \Phi(x_i)$

  – Equivalent to solving:
$$\min_{\alpha \in \mathbb{R}^n} \sum_{i=1}^{n} \ell(y_i, (K\alpha)_i) + \frac{\lambda}{2} \alpha^\top K \alpha$$

  – Kernel matrix $K_{ij} = k(x_i, x_j) = \Phi(x_i)^\top \Phi(x_j)$

Multiple kernel learning (MKL)
(Lanckriet et al., 2004b; Bach et al., 2004a)

- Sparse methods are linear!

- Sparsity with non-linearities

  - replace $f(x) = \sum_{j=1}^{p} w_j^\top x_j$ with $x \in \mathbb{R}^p$ and $w_j \in \mathbb{R}$

  - by $f(x) = \sum_{j=1}^{p} w_j^\top \Phi_j(x)$ with $x \in \mathcal{X}$, $\Phi_j(x) \in \mathcal{F}_j$ an $w_j \in \mathcal{F}_j$

- Replace the ℓ_1-norm $\sum_{j=1}^{p} |w_j|$ by "block" ℓ_1-norm $\sum_{j=1}^{p} \|w_j\|_2$

- Remarks

  - Hilbert space extension of the group Lasso (Yuan and Lin, 2006)
  - Alternative sparsity-inducing norms (Ravikumar et al., 2008)

Multiple kernel learning (MKL)
(Lanckriet et al., 2004b; Bach et al., 2004a)

- Multiple feature maps / kernels on $x \in \mathcal{X}$:

  - p "feature maps" $\Phi_j : \mathcal{X} \mapsto \mathcal{F}_j$, $j = 1, \ldots, p$.
  - Minimization with respect to $w_1 \in \mathcal{F}_1, \ldots, w_p \in \mathcal{F}_p$
  - Predictor: $f(x) = w_1^\top \Phi_1(x) + \cdots + w_p^\top \Phi_p(x)$

$$
\begin{array}{ccc}
& \Phi_1(x)^\top \quad w_1 & \\
\nearrow \qquad \vdots \qquad \vdots \qquad \searrow & \\
x \longrightarrow \Phi_j(x)^\top \quad w_j \longrightarrow w_1^\top \Phi_1(x) + \cdots + w_p^\top \Phi_p(x) \\
\searrow \qquad \vdots \qquad \vdots \qquad \nearrow & \\
& \Phi_p(x)^\top \quad w_p &
\end{array}
$$

  - Generalized additive models (Hastie and Tibshirani, 1990)

Regularization for multiple features

$$\Phi_1(x)^\top \quad w_1$$

$$x \longrightarrow \quad \Phi_j(x)^\top \quad w_j \quad \longrightarrow \quad w_1^\top \Phi_1(x) + \cdots + w_p^\top \Phi_p(x)$$

$$\Phi_p(x)^\top \quad w_p$$

- Regularization by $\sum_{j=1}^p \|w_j\|_2^2$ is equivalent to using $K = \sum_{j=1}^p K_j$
  - Summing kernels is equivalent to concatenating feature spaces

Regularization for multiple features

$$
\begin{array}{ccc}
 & \Phi_1(x)^\top \quad w_1 & \\
\nearrow & \vdots \qquad \vdots & \searrow \\
x \longrightarrow & \Phi_j(x)^\top \quad w_j \longrightarrow & w_1^\top \Phi_1(x) + \cdots + w_p^\top \Phi_p(x) \\
\searrow & \vdots \qquad \vdots & \nearrow \\
 & \Phi_p(x)^\top \quad w_p &
\end{array}
$$

- Regularization by $\sum_{j=1}^{p} \|w_j\|_2^2$ is equivalent to using $K = \sum_{j=1}^{p} K_j$

- Regularization by $\sum_{j=1}^{p} \|w_j\|_2$ imposes sparsity at the group level

- **Main questions when regularizing by block ℓ_1-norm**:

  1. Algorithms
  2. Analysis of sparsity inducing properties (Ravikumar et al., 2008; Bach, 2008b)
  3. Does it correspond to a specific combination of kernels?

General kernel learning

- **Proposition** (Lanckriet et al, 2004, Bach et al., 2005, Micchelli and Pontil, 2005):

$$
\begin{aligned}
G(K) &= \min_{w \in \mathcal{F}} \sum_{i=1}^{n} \ell(y_i, w^\top \Phi(x_i)) + \frac{\lambda}{2}\|w\|_2^2 \\
&= \max_{\alpha \in \mathbb{R}^n} -\sum_{i=1}^{n} \ell_i^*(\lambda \alpha_i) - \frac{\lambda}{2}\alpha^\top K \alpha
\end{aligned}
$$

  is a **convex** function of the kernel matrix K

- Theoretical learning bounds (Lanckriet et al., 2004, Srebro and Ben-David, 2006)

  – Less assumptions than sparsity-based bounds, but slower rates

Equivalence with kernel learning (Bach et al., 2004a)

- Block ℓ_1-norm problem:

$$\sum_{i=1}^{n} \ell(y_i, w_1^\top \Phi_1(x_i) + \cdots + w_p^\top \Phi_p(x_i)) + \frac{\lambda}{2} \left(\|w_1\|_2 + \cdots + \|w_p\|_2 \right)^2$$

- **Proposition**: Block ℓ_1-norm regularization is equivalent to minimizing with respect to η the optimal value $G(\sum_{j=1}^{p} \eta_j K_j)$

- (sparse) weights η obtained from optimality conditions

- dual parameters α optimal for $K = \sum_{j=1}^{p} \eta_j K_j$,

- **Single optimization problem for learning both η and α**

Proof of equivalence

$$\min_{w_1,\dots,w_p} \sum_{i=1}^{n} \ell\Big(y_i, \sum_{j=1}^{p} w_j^\top \Phi_j(x_i)\Big) + \lambda \Big(\sum_{j=1}^{p} \|w_j\|_2\Big)^2$$

$$= \min_{w_1,\dots,w_p} \min_{\sum_j \eta_j = 1} \sum_{i=1}^{n} \ell\Big(y_i, \sum_{j=1}^{p} w_j^\top \Phi_j(x_i)\Big) + \lambda \sum_{j=1}^{p} \|w_j\|_2^2/\eta_j$$

$$= \min_{\sum_j \eta_j = 1} \min_{\tilde{w}_1,\dots,\tilde{w}_p} \sum_{i=1}^{n} \ell\Big(y_i, \sum_{j=1}^{p} \eta_j^{1/2} \tilde{w}_j^\top \Phi_j(x_i)\Big) + \lambda \sum_{j=1}^{p} \|\tilde{w}_j\|_2^2 \text{ with } \tilde{w}_j = w_j \eta_j^{-1/2}$$

$$= \min_{\sum_j \eta_j = 1} \min_{\tilde{w}} \sum_{i=1}^{n} \ell\Big(y_i, \tilde{w}^\top \Psi_\eta(x_i)\Big) + \lambda \|\tilde{w}\|_2^2 \text{ with } \Psi_\eta(x) = (\eta_1^{1/2} \Phi_1(x), \dots, \eta_p^{1/2} \Phi_p(x))$$

- We have: $\Psi_\eta(x)^\top \Psi_\eta(x') = \sum_{j=1}^{p} \eta_j k_j(x, x')$ with $\sum_{j=1}^{p} \eta_j = 1$ (and $\eta \geqslant 0$)

Algorithms for the group Lasso / MKL

- Group Lasso

  – Block coordinate descent (Yuan and Lin, 2006)
  – Active set method (Roth and Fischer, 2008; Obozinski et al., 2009)
  – Nesterov's accelerated method (Liu et al., 2009)

- MKL

  – Dual ascent, e.g., sequential minimal optimization (Bach et al., 2004a)
  – η-trick + cutting-planes (Sonnenburg et al., 2006)
  – η-trick + projected gradient descent (Rakotomamonjy et al., 2008)
  – Active set (Bach, 2008c)

Applications of multiple kernel learning

- **Selection of hyperparameters for kernel methods**

- **Fusion from heterogeneous data sources** (Lanckriet et al., 2004a)

- Two strategies for kernel combinations:

  - Uniform combination $\Leftrightarrow$ ℓ_2-norm
  - Sparse combination $\Leftrightarrow$ ℓ_1-norm
  - MKL always leads to more interpretable models
  - MKL does not always lead to better predictive performance
    - $*$ In particular, with few well-designed kernels
    - $*$ Be careful with normalization of kernels (Bach et al., 2004b)

Applications of multiple kernel learning

- **Selection of hyperparameters for kernel methods**

- **Fusion from heterogeneous data sources** (Lanckriet et al., 2004a)

- Two strategies for kernel combinations:

  - Uniform combination $\Leftrightarrow \ell_2$-norm
  - Sparse combination $\Leftrightarrow \ell_1$-norm
  - MKL always leads to more interpretable models
  - MKL does not always lead to better predictive performance
    - ∗ In particular, with few well-designed kernels
    - ∗ Be careful with normalization of kernels (Bach et al., 2004b)

- **Sparse methods**: new possibilities and new features

Sparse methods for machine learning
Outline

- **Introduction - Overview**

- **Sparse linear estimation with the ℓ_1-norm**

  - Convex optimization and algorithms
  - Theoretical results

- **Structured sparse methods on vectors**

  - Groups of features / Multiple kernel learning
  - Extensions (hierarchical or overlapping groups)

- **Sparse methods on matrices**

  - Multi-task learning
  - Matrix factorization (low-rank, sparse PCA, dictionary learning)

Lasso - Two main recent theoretical results

1. **Support recovery condition**

2. **Exponentially many irrelevant variables**: under appropriate assumptions, consistency is possible as long as

$$\log p = O(n)$$

Lasso - Two main recent theoretical results

1. **Support recovery condition**

2. **Exponentially many irrelevant variables**: under appropriate assumptions, consistency is possible as long as

$$\log p = O(n)$$

- Question: is it possible to build a sparse algorithm that can learn from more than 10^{80} features?

Lasso - Two main recent theoretical results

1. **Support recovery condition**

2. **Exponentially many irrelevant variables**: under appropriate assumptions, consistency is possible as long as

$$\log p = O(n)$$

- Question: is it possible to build a sparse algorithm that can learn from more than 10^{80} features?

  – **Some type of recursivity/factorization is needed!**

Non-linear variable selection

- Given $x = (x_1, \ldots, x_q) \in \mathbb{R}^q$, find function $f(x_1, \ldots, x_q)$ which depends only on a few variables

- Sparse generalized additive models (e.g., MKL):

  - restricted to $f(x_1, \ldots, x_q) = f_1(x_1) + \cdots + f_q(x_q)$

- Cosso (Lin and Zhang, 2006):

  - restricted to $f(x_1, \ldots, x_q) = \displaystyle\sum_{J \subset \{1,\ldots,q\}, \ |J| \leqslant 2} f_J(x_J)$

Non-linear variable selection

- Given $x = (x_1, \ldots, x_q) \in \mathbb{R}^q$, find function $f(x_1, \ldots, x_q)$ which depends only on a few variables

- Sparse generalized additive models (e.g., MKL):

  – restricted to $f(x_1, \ldots, x_q) = f_1(x_1) + \cdots + f_q(x_q)$

- Cosso (Lin and Zhang, 2006):

  – restricted to $f(x_1, \ldots, x_q) = \displaystyle\sum_{J \subset \{1,\ldots,q\}, \ |J| \leqslant 2} f_J(x_J)$

- Universally consistent non-linear selection requires all 2^q subsets

$$f(x_1, \ldots, x_q) = \sum_{J \subset \{1,\ldots,q\}} f_J(x_J)$$

Hierarchical kernel learning (Bach, 2008c)

- Many kernels can be decomposed as a sum of many "small" kernels indexed by a certain set V: $\boxed{k(x,x') = \sum_{v \in V} k_v(x,x')}$

- Example with $x = (x_1, \ldots, x_q) \in \mathbb{R}^q$ ($\Rightarrow$ non linear variable selection)
  - Gaussian/ANOVA kernels: $p = \#(V) = 2^q$

$$\prod_{j=1}^{q} \left(1 + e^{-\alpha(x_j - x'_j)^2}\right) = \sum_{J \subset \{1,\ldots,q\}} \prod_{j \in J} e^{-\alpha(x_j - x'_j)^2} = \sum_{J \subset \{1,\ldots,q\}} e^{-\alpha \|x_J - x'_J\|_2^2}$$

  - NB: decomposition is related to Cosso (Lin and Zhang, 2006)

- **Goal**: learning sparse combination $\sum_{v \in V} \eta_v k_v(x,x')$

- Universally consistent non-linear variable selection requires all subsets

Restricting the set of active kernels

- Assume one separate predictor w_v for each kernel k_v

  – Final prediction: $f(x) = \sum_{v \in V} w_v^\top \Phi_v(x)$

- With flat structure

  – Consider block ℓ_1-norm: $\sum_{v \in V} d_v \|w_v\|_2$
  – cannot avoid being linear in $p = \#(V) = 2^q$

- Using the structure of the small kernels

  1. for computational reasons
  2. to allow more irrelevant variables

Restricting the set of active kernels

- V is endowed with a directed acyclic graph (DAG) structure:
  select a kernel only after all of its ancestors have been selected

- Gaussian kernels: $V = $ power set of $\{1, \ldots, q\}$ with inclusion DAG

  – Select a subset only after all its subsets have been selected
Restricting the set of active kernels

- V is endowed with a directed acyclic graph (DAG) structure:
  select a kernel only after all of its ancestors have been selected

- Gaussian kernels: $V =$ power set of $\{1, \dots, q\}$ with inclusion DAG

  – Select a subset only after all its subsets have been selected

DAG-adapted norm (Zhao et al., 2009; Bach, 2008c)

- Graph-based structured regularization

  - $D(v)$ is the set of descendants of $v \in V$:

  $$\sum_{v \in V} \|w_{D(v)}\|_2 = \sum_{v \in V} \left(\sum_{t \in D(v)} \|w_t\|_2^2 \right)^{1/2}$$

- Main property: If v is selected, so are all its ancestors

DAG-adapted norm (Zhao et al., 2009; Bach, 2008c)

- Graph-based structured regularization

  - $D(v)$ is the set of descendants of $v \in V$:

$$\sum_{v \in V} \|w_{D(v)}\|_2 = \sum_{v \in V} \left(\sum_{t \in D(v)} \|w_t\|_2^2 \right)^{1/2}$$

- Main property: If v is selected, so are all its ancestors

DAG-adapted norm (Zhao et al., 2009; Bach, 2008c)

- Graph-based structured regularization

  - $D(v)$ is the set of descendants of $v \in V$:

$$\sum_{v \in V} \|w_{D(v)}\|_2 = \sum_{v \in V} \left(\sum_{t \in D(v)} \|w_t\|_2^2 \right)^{1/2}$$

- Main property: If v is selected, so are all its ancestors

DAG-adapted norm (Zhao et al., 2009; Bach, 2008c)

- Graph-based structured regularization

  - $D(v)$ is the set of descendants of $v \in V$:

$$\sum_{v \in V} \|w_{D(v)}\|_2 = \sum_{v \in V} \left(\sum_{t \in D(v)} \|w_t\|_2^2 \right)^{1/2}$$

- Main property: If v is selected, so are all its ancestors

DAG-adapted norm (Zhao et al., 2009; Bach, 2008c)

- Graph-based structured regularization

  - $D(v)$ is the set of descendants of $v \in V$:

  $$\sum_{v \in V} \|w_{D(v)}\|_2 = \sum_{v \in V} \left(\sum_{t \in D(v)} \|w_t\|_2^2 \right)^{1/2}$$

- Main property: If v is selected, so are all its ancestors

- **Hierarchical kernel learning** (Bach, 2008c) :

  - **polynomial-time** algorithm for this norm
  - **necessary/sufficient conditions** for consistent kernel selection
  - **Scaling between p, q, n** for consistency
  - **Applications** to variable selection or other kernels

DAG-adapted norm (Zhao et al., 2009; Bach, 2008c)

- Graph-based structured regularization

  - $\mathrm{D}(v)$ is the set of descendants of $v \in V$:

$$\sum_{v \in V} d_v \|w_{\mathrm{D}(v)}\|_2 = \sum_{v \in V} d_v \left(\sum_{t \in \mathrm{D}(v)} \|w_t\|_2^2 \right)^{1/2}$$

- Main property: If v is selected, so are all its ancestors

- **Hierarchical kernel learning** (Bach, 2008c) :

  - **polynomial-time** algorithm for this norm
  - **necessary/sufficient conditions** for consistent kernel selection
  - **Scaling between p, q, n** for consistency
  - **Applications** to variable selection or other kernels

Scaling between p, n and other graph-related quantities

$$n \qquad = \quad \text{number of observations}$$
$$p \qquad = \quad \text{number of vertices in the DAG}$$
$$\deg(V) \quad = \quad \text{maximum out degree in the DAG}$$
$$\text{num}(V) \quad = \quad \text{number of connected components in the DAG}$$

- **Proposition** (Bach, 2009a): Assume consistency condition satisfied, Gaussian noise and data generated from a sparse function, then the support is recovered with high-probability as soon as:

$$\log \deg(V) + \log \text{num}(V) = O(n)$$

Scaling between p, n and other graph-related quantities

$$
\begin{aligned}
n &= \text{number of observations} \\
p &= \text{number of vertices in the DAG} \\
\deg(V) &= \text{maximum out degree in the DAG} \\
\mathrm{num}(V) &= \text{number of connected components in the DAG}
\end{aligned}
$$

- **Proposition** (Bach, 2009a): Assume consistency condition satisfied, Gaussian noise and data generated from a sparse function, then the support is recovered with high-probability as soon as:

$$
\log \deg(V) + \log \mathrm{num}(V) = O(n)
$$

- Unstructured case: $\mathrm{num}(V) = p \Rightarrow \boxed{\log p = O(n)}$

- Power set of q elements: $\deg(V) = q \Rightarrow \boxed{\log q = \log \log p = O(n)}$

Mean-square errors (regression)

Extensions to other kernels

- Extension to graph kernels, string kernels, pyramid match kernels
- Exploring large feature spaces with structured sparsity-inducing norms

  - Opposite view than traditional kernel methods
  - Interpretable models

- **Other structures than hierarchies or DAGs**

Sparse methods for machine learning
Outline

- **Introduction - Overview**

- **Sparse linear estimation with the ℓ_1-norm**

  - Convex optimization and algorithms
  - Theoretical results

- **Structured sparse methods on vectors**

  - Groups of features / Multiple kernel learning
  - Extensions (hierarchical or overlapping groups)

- **Sparse methods on matrices**

  - Multi-task learning
  - Matrix factorization (low-rank, sparse PCA, dictionary learning)

Grouped variables

- Supervised learning with known groups:

  - The ℓ_1-ℓ_2 norm

  $$\sum_{G \in \mathbf{G}} \|w_G\|_2 = \sum_{G \in \mathbf{G}} \Big(\sum_{j \in G} w_j^2 \Big)^{1/2}, \text{ with } \mathbf{G} \text{ a partition of } \{1, \ldots, p\}$$

  - The ℓ_1-ℓ_2 norm sets to zero non-overlapping groups of variables (as opposed to single variables for the ℓ_1 norm)

Grouped variables

- Supervised learning with known groups:

  - The ℓ_1-ℓ_2 norm

  $$\sum_{G \in \mathbf{G}} \|w_G\|_2 = \sum_{G \in \mathbf{G}} \Big(\sum_{j \in G} w_j^2\Big)^{1/2}, \text{ with } \mathbf{G} \text{ a partition of } \{1, \ldots, p\}$$

  - The ℓ_1-ℓ_2 norm sets to zero non-overlapping groups of variables (as opposed to single variables for the ℓ_1 norm).

- However, the ℓ_1-ℓ_2 norm encodes **fixed/static prior information**, requires to know in advance how to group the variables

- What happens if the set of groups $\mathbf{G}$ is not a partition anymore?

Structured Sparsity (Jenatton et al., 2009a)

- When penalizing by the ℓ_1-ℓ_2 norm

$$\sum_{G \in \mathbf{G}} \|w_G\|_2 = \sum_{G \in \mathbf{G}} \Big(\sum_{j \in G} w_j^2 \Big)^{1/2}$$

  - The ℓ_1 norm induces sparsity at the group level:
    * Some w_G's are set to zero
  - Inside the groups, the ℓ_2 norm does not promote sparsity

- Intuitively, the zero pattern of w is given by

$$\{j \in \{1, \ldots, p\}; \ w_j = 0\} = \bigcup_{G \in \mathbf{G}'} G \ \text{ for some } \mathbf{G}' \subseteq \mathbf{G}.$$

- This intuition is actually true and can be formalized

- Selection of contiguous patterns on a sequence, $p = 6$
    − $\mathbf{G}$ is the set of blue groups

    − Any union of blue groups set to zero leads to the selection of a contiguous pattern

- Selection of rectangles on a 2-D grids, $p = 25$
  – $\mathbf{G}$ is the set of blue/green groups (with their complements, not displayed)

  – Any union of blue/green groups set to zero leads to the selection of a rectangle

Examples of set of groups $\mathbb{G}$ (3/3)

- Selection of diamond-shaped patterns on a 2-D grids, $p = 25$
- – It is possible to extent such settings to 3-D space, or more complex topologies
- – **See applications later (sparse PCA)**

Relationship between G and Zero Patterns (Jenatton, Audibert, and Bach, 2009a)

- **G** → **Zero patterns**:

  – by generating the union-closure of **G**

- **Zero patterns** → **G**:

  – Design groups **G** from any **union-closed set** of **zero** patterns
  – Design groups **G** from any **intersection-closed set** of **non-zero** patterns

Overview of other work on structured sparsity

- Specific hierarchical structure (Zhao et al., 2009; Bach, 2008c)

- Union-closed (as opposed to intersection-closed) family of nonzero patterns (Jacob et al., 2009; Baraniuk et al., 2008)

- Nonconvex penalties based on information-theoretic criteria with greedy optimization (Huang et al., 2009)

Sparse methods for machine learning
Outline

- **Introduction - Overview**

- **Sparse linear estimation with the ℓ_1-norm**

  - Convex optimization and algorithms
  - Theoretical results

- **Structured sparse methods on vectors**

  - Groups of features / Multiple kernel learning
  - Extensions (hierarchical or overlapping groups)

- **Sparse methods on matrices**

  - Multi-task learning
  - Matrix factorization (low-rank, sparse PCA, dictionary learning)

Learning on matrices - Image denoising

- Simultaneously denoise all patches of a given image

- Example from Mairal, Bach, Ponce, Sapiro, and Zisserman (2009c)
Learning on matrices - Collaborative filtering

- Given $n_{\mathcal{X}}$ "movies" $\mathbf{x} \in \mathcal{X}$ and $n_{\mathcal{Y}}$ "customers" $\mathbf{y} \in \mathcal{Y}$,

- predict the "rating" $z(\mathbf{x}, \mathbf{y}) \in \mathcal{Z}$ of customer $\mathbf{y}$ for movie $\mathbf{x}$

- Training data: large $n_{\mathcal{X}} \times n_{\mathcal{Y}}$ incomplete matrix $\mathbf{Z}$ that describes the known ratings of some customers for some movies

- **Goal**: complete the matrix.
Learning on matrices - Source separation

- Single microphone (Benaroya et al., 2006; Févotte et al., 2009)

Signal x

Log–power spectrogram
Learning on matrices - Multi-task learning

- k linear prediction tasks on same covariates $\mathbf{x} \in \mathbb{R}^p$

  - k weight vectors $\mathbf{w}_j \in \mathbb{R}^p$
  - Joint matrix of predictors $\mathbf{W} = (\mathbf{w}_1, \ldots, \mathbf{w}_k) \in \mathbb{R}^{p \times k}$

- Classical application

  - Multi-category classification (one task per class) (Amit et al., 2007)

- **Share parameters between tasks**

- **Joint variable selection** (Obozinski et al., 2009)

  - Select variables which are predictive for all tasks

- **Joint feature selection** (Pontil et al., 2007)

  - Construct linear features common to all tasks

Matrix factorization - Dimension reduction

- Given data matrix $\mathbf{X} = (\mathbf{x}_1, \ldots, \mathbf{x}_n) \in \mathbb{R}^{p \times n}$

  – **Principal component analysis**: $\boxed{\mathbf{x}_i \approx \mathbf{D}\boldsymbol{\alpha}_i \Rightarrow \mathbf{X} = \mathbf{D}\mathbf{A}}$
  – **K-means**: $\boxed{\mathbf{x}_i \approx \mathbf{d}_k \Rightarrow \mathbf{X} = \mathbf{D}\mathbf{A}}$
Two types of sparsity for matrices $\mathbf{M} \in \mathbb{R}^{n \times p}$
I - Directly on the elements of $\mathbf{M}$

- Many zero elements: $\mathbf{M}_{ij} = 0$
- Many zero rows (or columns): $(\mathbf{M}_{i1}, \ldots, \mathbf{M}_{ip}) = 0$
Two types of sparsity for matrices $\mathbf{M} \in \mathbb{R}^{n \times p}$
II - Through a factorization of $\mathbf{M} = \mathbf{U}\mathbf{V}^\top$

- Matrix $\mathbf{M} = \mathbf{U}\mathbf{V}^\top$, $\mathbf{U} \in \mathbb{R}^{n \times k}$ and $\mathbf{V} \in \mathbb{R}^{p \times k}$

- **Low rank**: m small
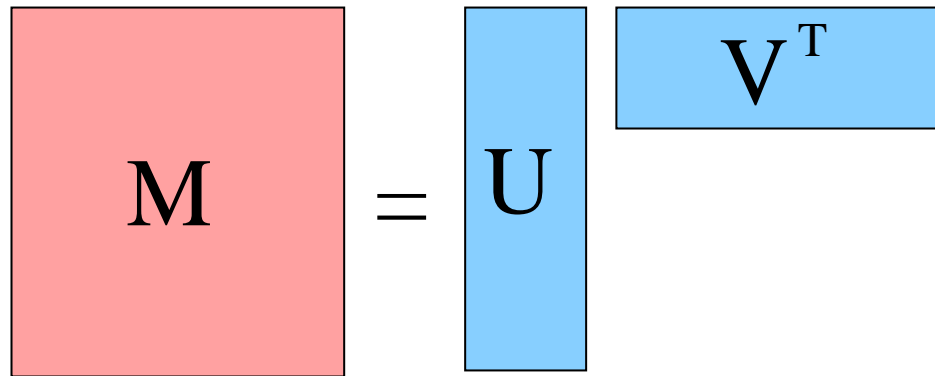

- **Sparse decomposition**: $\mathbf{U}$ sparse
Structured sparse matrix factorizations

- Matrix $\mathbf{M} = \mathbf{U}\mathbf{V}^\top$, $\mathbf{U} \in \mathbb{R}^{n \times k}$ and $\mathbf{V} \in \mathbb{R}^{p \times k}$

- **Structure on $\mathbf{U}$ and/or $\mathbf{V}$**

  - Low-rank: $\mathbf{U}$ and $\mathbf{V}$ have few columns
  - Dictionary learning / sparse PCA: $\mathbf{U}$ has many zeros
  - Clustering (k-means): $\mathbf{U} \in \{0,1\}^{n \times m}$, $\mathbf{U}\mathbf{1} = \mathbf{1}$
  - Pointwise positivity: non negative matrix factorization (NMF)
  - Specific patterns of zeros (Jenatton et al., 2010)
  - Low-rank + sparse (Candès et al., 2009)
  - etc.

- **Many applications**

- **Many open questions** (Algorithms, identifiability, etc.)

Multi-task learning

- Joint matrix of predictors $W = (w_1, \ldots, w_k) \in \mathbb{R}^{p \times k}$

- **Joint variable selection** (Obozinski et al., 2009)

  - Penalize by the sum of the norms of rows of W (group Lasso)
  - Select variables which are predictive for all tasks

Multi-task learning

- Joint matrix of predictors $W = (w_1, \ldots, w_k) \in \mathbb{R}^{p \times k}$

- **Joint variable selection** (Obozinski et al., 2009)

  – Penalize by the sum of the norms of rows of W (group Lasso)
  – Select variables which are predictive for all tasks

- **Joint feature selection** (Pontil et al., 2007)

  – Penalize by the trace-norm (see later)
  – Construct linear features common to all tasks

- Theory: allows number of observations which is sublinear in the number of tasks (Obozinski et al., 2008; Lounici et al., 2009)

- Practice: more interpretable models, slightly improved performance

Low-rank matrix factorizations
Trace norm

- Given a matrix $\mathbf{M} \in \mathbb{R}^{n \times p}$

  - Rank of $\mathbf{M}$ is the minimum size m of **all** factorizations of $\mathbf{M}$ into $\mathbf{M} = \mathbf{U}\mathbf{V}^\top$, $\mathbf{U} \in \mathbb{R}^{n \times m}$ and $\mathbf{V} \in \mathbb{R}^{p \times m}$
  - Singular value decomposition: $\mathbf{M} = \mathbf{U}\operatorname{Diag}(\mathbf{s})\mathbf{V}^\top$ where $\mathbf{U}$ and $\mathbf{V}$ have orthonormal columns and $\mathbf{s} \in \mathbb{R}^m_+$ are singular values

- Rank of $\mathbf{M}$ equal to the number of non-zero singular values

Low-rank matrix factorizations
Trace norm

- Given a matrix $\mathbf{M} \in \mathbb{R}^{n \times p}$

    - Rank of $\mathbf{M}$ is the minimum size m of **all** factorizations of $\mathbf{M}$ into $\mathbf{M} = \mathbf{U}\mathbf{V}^\top$, $\mathbf{U} \in \mathbb{R}^{n \times m}$ and $\mathbf{V} \in \mathbb{R}^{p \times m}$
    - Singular value decomposition: $\mathbf{M} = \mathbf{U}\operatorname{Diag}(\mathbf{s})\mathbf{V}^\top$ where $\mathbf{U}$ and $\mathbf{V}$ have orthonormal columns and $\mathbf{s} \in \mathbb{R}^m_+$ are singular values

- Rank of $\mathbf{M}$ equal to the number of non-zero singular values

- **Trace-norm (a.k.a. nuclear norm)** $=$ sum of singular values

- Convex function, leads to a semi-definite program (Fazel et al., 2001)

- First used for collaborative filtering (Srebro et al., 2005)

Results for the trace norm

- Rank recovery condition (Bach, 2008d)

  – The Hessian of the loss around the asymptotic solution should be close to diagonal

- Sufficient condition for exact rank minimization (Recht et al., 2009)

- High-dimensional inference for noisy matrix completion (Srebro et al., 2005; Candès and Plan, 2009a)

  – May recover entire matrix from slightly more entries than the minimum of the two dimensions

- **Efficient algorithms**:
  – First-order methods based on the singular value decomposition (see, e.g., Mazumder et al., 2009)
  – Low-rank formulations (Rennie and Srebro, 2005; Abernethy et al., 2009)

Spectral regularizations

- Extensions to any functions of singular values

- Extensions to bilinear forms (Abernethy et al., 2009)

$$(\mathbf{x}, \mathbf{y}) \mapsto \Phi(\mathbf{x})^\top B \Psi(\mathbf{y})$$

  on features $\Phi(\mathbf{x}) \in \mathbb{R}^{f_\mathcal{X}}$ and $\Psi(\mathbf{y}) \in \mathbb{R}^{f_\mathcal{Y}}$, and $B \in \mathbb{R}^{f_\mathcal{X} \times f_\mathcal{Y}}$

- Collaborative filtering with attributes

- **Representer theorem**: the solution must be of the form

$$B = \sum_{i=1}^{n_\mathcal{X}} \sum_{j=1}^{n_\mathcal{Y}} \alpha_{ij} \Psi(\mathbf{x}_i) \Phi(\mathbf{y}_j)^\top$$

- Only norms invariant by orthogonal transforms (Argyriou et al., 2009)

Sparse principal component analysis

- Given data $\mathbf{X} = (\mathbf{x}_1^\top, \ldots, \mathbf{x}_n^\top) \in \mathbb{R}^{p \times n}$, two views of PCA:

  - **Analysis view**: find the projection $\mathbf{d} \in \mathbb{R}^p$ of maximum variance (with deflation to obtain more components)
  - **Synthesis view**: find the basis $\mathbf{d}_1, \ldots, \mathbf{d}_k$ such that all $\mathbf{x}_i$ have low reconstruction error when decomposed on this basis

- For regular PCA, the two views are equivalent
Sparse principal component analysis

- Given data $\mathbf{X} = (\mathbf{x}_1^\top, \ldots, \mathbf{x}_n^\top) \in \mathbb{R}^{p \times n}$, two views of PCA:

  - **Analysis view**: find the projection $\mathbf{d} \in \mathbb{R}^p$ of maximum variance (with deflation to obtain more components)
  - **Synthesis view**: find the basis $\mathbf{d}_1, \ldots, \mathbf{d}_k$ such that all $\mathbf{x}_i$ have low reconstruction error when decomposed on this basis

- For regular PCA, the two views are equivalent

- **Sparse extensions**

  - Interpretability
  - High-dimensional inference
  - Two views are differents
    * For analysis view, see d'Aspremont, Bach, and El Ghaoui (2008)

Sparse principal component analysis
Synthesis view

- Find $\mathbf{d}_1, \dots, \mathbf{d}_k \in \mathbb{R}^p$ **sparse** so that

$$\sum_{i=1}^{n} \min_{\boldsymbol{\alpha}_i \in \mathbb{R}^m} \left\| \mathbf{x}_i - \sum_{j=1}^{k} (\boldsymbol{\alpha}_i)_j \mathbf{d}_j \right\|_2^2 = \sum_{i=1}^{n} \min_{\boldsymbol{\alpha}_i \in \mathbb{R}^m} \left\| \mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i \right\|_2^2 \text{ is small}$$

  - Look for $\mathbf{A} = (\boldsymbol{\alpha}_1, \dots, \boldsymbol{\alpha}_n) \in \mathbb{R}^{k \times n}$ and $\mathbf{D} = (\mathbf{d}_1, \dots, \mathbf{d}_k) \in \mathbb{R}^{p \times k}$ such that $\mathbf{D}$ is sparse and $\|\mathbf{X} - \mathbf{D}\mathbf{A}\|_F^2$ is small

Sparse principal component analysis
Synthesis view

- Find $\mathbf{d}_1, \ldots, \mathbf{d}_k \in \mathbb{R}^p$ **sparse** so that

$$\sum_{i=1}^{n} \min_{\boldsymbol{\alpha}_i \in \mathbb{R}^m} \left\| \mathbf{x}_i - \sum_{j=1}^{k} (\boldsymbol{\alpha}_i)_j \mathbf{d}_j \right\|_2^2 = \sum_{i=1}^{n} \min_{\boldsymbol{\alpha}_i \in \mathbb{R}^m} \left\| \mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i \right\|_2^2 \text{ is small}$$

  – Look for $\mathbf{A} = (\boldsymbol{\alpha}_1, \ldots, \boldsymbol{\alpha}_n) \in \mathbb{R}^{k \times n}$ and $\mathbf{D} = (\mathbf{d}_1, \ldots, \mathbf{d}_k) \in \mathbb{R}^{p \times k}$ such that $\mathbf{D}$ is sparse and $\|\mathbf{X} - \mathbf{D}\mathbf{A}\|_F^2$ is small

- Sparse formulation (Witten et al., 2009; Bach et al., 2008)

  – Penalize/constrain $\mathbf{d}_j$ by the ℓ_1-norm for sparsity
  – Penalize/constrain $\boldsymbol{\alpha}_i$ by the ℓ_2-norm to avoid trivial solutions

$$\min_{\mathbf{D}, \mathbf{A}} \sum_{i=1}^{n} \|\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i\|_2^2 + \lambda \sum_{j=1}^{k} \|\mathbf{d}_j\|_1 \text{ s.t. } \forall i, \|\boldsymbol{\alpha}_i\|_2 \leqslant 1$$

Sparse PCA vs. dictionary learning

- **Sparse PCA**: $\mathbf{x}_i \approx \mathbf{D}\boldsymbol{\alpha}_i$, $\mathbf{D}$ sparse
Sparse PCA vs. dictionary learning

- **Sparse PCA**: $\mathbf{x}_i \approx \mathbf{D}\boldsymbol{\alpha}_i$, $\mathbf{D}$ sparse
- **Dictionary learning**: $\mathbf{x}_i \approx \mathbf{D}\boldsymbol{\alpha}_i$, $\boldsymbol{\alpha}_i$ sparse
Structured matrix factorizations (Bach et al., 2008)

$$\min_{\mathbf{D},\mathbf{A}} \sum_{i=1}^{n} \|\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i\|_2^2 + \lambda \sum_{j=1}^{k} \|\mathbf{d}_j\|_\star \text{ s.t. } \forall i, \|\boldsymbol{\alpha}_i\|_\bullet \leqslant 1$$

$$\min_{\mathbf{D},\mathbf{A}} \sum_{i=1}^{n} \|\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i\|_2^2 + \lambda \sum_{i=1}^{n} \|\boldsymbol{\alpha}_i\|_\bullet \text{ s.t. } \forall j, \|\mathbf{d}_j\|_\star \leqslant 1$$

- Optimization by alternating minimization (non-convex)

- $\boldsymbol{\alpha}_i$ decomposition coefficients (or "code"), $\mathbf{d}_j$ dictionary elements

- Two related/equivalent problems:

  - **Sparse PCA** = **sparse dictionary** (ℓ_1-norm on $\mathbf{d}_j$)
  - **Dictionary learning** = **sparse decompositions** (ℓ_1-norm on $\boldsymbol{\alpha}_i$)
    (Olshausen and Field, 1997; Elad and Aharon, 2006; Lee et al., 2007)

Dictionary learning for image denoising

$$\underbrace{\mathbf{x}}_{\text{measurements}} = \underbrace{\mathbf{y}}_{\text{original image}} + \underbrace{\varepsilon}_{\text{noise}}$$

Dictionary learning for image denoising

- **Solving the denoising problem** (Elad and Aharon, 2006)

  - Extract all overlapping 8×8 patches $\mathbf{x}_i \in \mathbb{R}^{64}$
  - Form the matrix $\mathbf{X} = (\mathbf{x}_1^\top, \ldots, \mathbf{x}_n^\top) \in \mathbb{R}^{n \times 64}$
  - Solve a matrix factorization problem:

  $$\min_{\mathbf{D}, \mathbf{A}} ||\mathbf{X} - \mathbf{D}\mathbf{A}||_F^2 = \min_{\mathbf{D}, \mathbf{A}} \sum_{i=1}^{n} ||\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i||_2^2$$

  where $\mathbf{A}$ is **sparse**, and $\mathbf{D}$ is the **dictionary**
  - Each patch is decomposed into $\mathbf{x}_i = \mathbf{D}\boldsymbol{\alpha}_i$
  - Average the reconstruction $\mathbf{D}\boldsymbol{\alpha}_i$ of each patch $\mathbf{x}_i$ to reconstruct a full-sized image

- The number of patches n is large ($=$ number of pixels)

Online optimization for dictionary learning

$$\min_{\mathbf{A} \in \mathbb{R}^{k \times n}, \mathbf{D} \in \mathcal{C}} \sum_{i=1}^{n} ||\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i||_2^2 + \lambda ||\boldsymbol{\alpha}_i||_1$$

$$\mathcal{C} \triangleq \{\mathbf{D} \in \mathbb{R}^{p \times k} \text{ s.t. } \forall j = 1, \ldots, k, \ ||\mathbf{d}_j||_2 \leqslant 1\}.$$

- Classical optimization alternates between $\mathbf{D}$ and $\mathbf{A}$

- Good results, but very slow !

Online optimization for dictionary learning

$$\min_{\mathbf{A} \in \mathbb{R}^{k \times n}, \mathbf{D} \in \mathcal{C}} \sum_{i=1}^{n} ||\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i||_2^2 + \lambda ||\boldsymbol{\alpha}_i||_1$$

$$\mathcal{C} \triangleq \{\mathbf{D} \in \mathbb{R}^{p \times k} \quad \text{s.t.} \quad \forall j = 1, \dots, k, \quad ||\mathbf{d}_j||_2 \leqslant 1\}.$$

- Classical optimization alternates between $\mathbf{D}$ and $\mathbf{A}$.

- Good results, but very slow !

- **Online learning** (Mairal, Bach, Ponce, and Sapiro, 2009a) can

  - handle potentially infinite datasets
  - adapt to dynamic training sets

- **Simultaneous sparse coding** (Mairal et al., 2009c)

  - Links with NL-means (Buades et al., 2008)

Denoising result
(Mairal, Bach, Ponce, Sapiro, and Zisserman, 2009c)

Denoising result
(Mairal, Bach, Ponce, Sapiro, and Zisserman, 2009c)

What does the dictionary D look like?

Inpainting a 12-Mpixel photograph

Inpainting a 12-Mpixel photograph

Inpainting a 12-Mpixel photograph

Inpainting a 12-Mpixel photograph

Sparse structured PCA
(Jenatton, Obozinski, and Bach, 2009b)

- Learning **sparse and structured dictionary elements**:

$$
\min_{\substack{\mathbf{A} \in \mathbb{R}^{k \times n} \\ \mathbf{D} \in \mathbb{R}^{p \times k}}} \sum_{i=1}^{n} \|\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i\|_2^2 + \lambda \sum_{j=1}^{p} \psi(\mathbf{d}_j) \text{ s.t. } \forall i, \ \|\boldsymbol{\alpha}_i\|_2 \leq 1
$$

- Structure of the dictionary elements determined by the choice of overlapping groups $\mathbf{G}$ (and thus ψ)

- Efficient learning procedures through "η-tricks"

  - Reweighted ℓ_2: $\displaystyle\sum_{G \in \mathbf{G}} \|\mathbf{y}_G\|_2 = \min_{\eta_G \geqslant 0, G \in \mathbf{G}} \frac{1}{2} \sum_{G \in \mathbf{G}} \left\{ \frac{\|\mathbf{y}_G\|_2^2}{\eta_G} + \eta_G \right\}$

Application to face databases (1/3)

raw data   (unstructured) NMF

- NMF obtains partially local features

Application to face databases (2/3)
(unstructured) sparse PCA   Structured sparse PCA

- Enforce selection of convex nonzero patterns $\Rightarrow$ robustness to occlusion

Application to face databases (2/3)

(unstructured) sparse PCA   Structured sparse PCA
- Enforce selection of convex nonzero patterns $\Rightarrow$ robustness to occlusion

Application to face databases (3/3)

- Quantitative performance evaluation on classification task
Dictionary learning vs. sparse structured PCA
Exchange roles of $\mathbf{D}$ and $\mathbf{A}$

- Sparse structured PCA (sparse and structured dictionary elements):

$$\min_{\substack{\mathbf{A} \in \mathbb{R}^{k \times n} \\ \mathbf{D} \in \mathbb{R}^{p \times k}}} \sum_{i=1}^{n} \|\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i\|_2^2 + \lambda \sum_{j=1}^{k} \psi(\mathbf{d}_j) \text{ s.t. } \forall i, \ \|\boldsymbol{\alpha}_i\|_2 \leq 1.$$

- Dictionary learning with structured sparsity for $\boldsymbol{\alpha}$:

$$\min_{\substack{\mathbf{A} \in \mathbb{R}^{k \times n} \\ \mathbf{D} \in \mathbb{R}^{p \times k}}} \sum_{i=1}^{n} \|\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i\|_2^2 + \lambda \psi(\boldsymbol{\alpha}_i) \text{ s.t. } \forall j, \ \|\mathbf{d}_j\|_2 \leq 1.$$

Hierarchical dictionary learning
(Jenatton, Mairal, Obozinski, and Bach, 2010)

- Structure on codes $\boldsymbol{\alpha}$ (not on dictionary $\mathbf{D}$)

- Hierarchical penalization: $\psi(\boldsymbol{\alpha}) = \sum_{G \in \mathbf{G}} \|\boldsymbol{\alpha}_G\|_2$ where groups G in $\mathbf{G}$ are equal to set of descendants of some nodes in a tree

- Variable selected after its ancestors (Zhao et al., 2009; Bach, 2008c)

Hierarchical dictionary learning
## Efficient optimization

$$\min_{\substack{\mathbf{A}\in\mathbb{R}^{k\times n} \\ \mathbf{D}\in\mathbb{R}^{p\times k}}} \sum_{i=1}^{n} \|\mathbf{x}_i - \mathbf{D}\boldsymbol{\alpha}_i\|_2^2 + \lambda\psi(\boldsymbol{\alpha}_i) \text{ s.t. } \forall j, \ \|\mathbf{d}_j\|_2 \leq 1.$$

- Minimization with respect to $\boldsymbol{\alpha}_i$: regularized least-squares

  – Many algorithms dedicated to the ℓ_1-norm $\psi(\boldsymbol{\alpha}) = \|\boldsymbol{\alpha}\|_1$

- Proximal methods : first-order methods with optimal convergence rate (Nesterov, 2007; Beck and Teboulle, 2009)

  – Requires solving many times $\min_{\boldsymbol{\alpha}\in\mathbb{R}^p} \frac{1}{2}\|\mathbf{y} - \boldsymbol{\alpha}\|_2^2 + \lambda\psi(\boldsymbol{\alpha})$

- Tree-structured regularization : **Efficient linear time algorithm based on primal-dual decomposition** (Jenatton et al., 2010)

Hierarchical dictionary learning
Application to image denoising

- Reconstruction of 100,000 8×8 natural images patches

  - Remove randomly subsampled pixels
  - Reconstruct with matrix factorization and structured sparsity

noise	50 %	60 %	70 %	80 %	90 %
flat	19.3 ± 0.1	26.8 ± 0.1	36.7 ± 0.1	50.6 ± 0.0	72.1 ± 0.0
tree	18.6 ± 0.1	25.7 ± 0.1	35.0 ± 0.1	48.0 ± 0.0	65.9 ± 0.3
Application to image denoising - Dictionary tree
Hierarchical dictionary learning
Modelling of text corpora

- Each document is modelled through word counts

- Low-rank matrix factorization of word-document matrix

- Probabilistic topic models (Blei et al., 2003a)

  – Similar structures based on non parametric Bayesian methods (Blei et al., 2004)
  – **Can we achieve similar performance with simple matrix factorization formulation?**

Hierarchical dictionary learning
Modelling of text corpora

Modelling of text corpora

- Comparison on predicting newsgroup article subjects:
Alternative usages of dictionary learning

- Uses the "code" U as representation of observations for subsequent processing (Raina et al., 2007; Yang et al., 2009)

- Adapt dictionary elements to specific tasks (Mairal et al., 2009b)

  – Discriminative training for weakly supervised pixel classification (Mairal et al., 2008)

Probabilistic topic models and matrix factorization
- **Latent Dirichlet allocation** (Blei et al., 2003b)

  – For a document, sample $\theta \in \mathbb{R}^k$ from a Dirichlet(α)
  – For the n-th word of the same document,
    * sample a topic z_n from a multinomial with parameter θ
    * sample a word w_n from a multinomial with parameter $\beta(z_n,:)$

Probabilistic topic models and matrix factorization
- **Latent Dirichlet allocation** (Blei et al., 2003b)

  - For a document, sample $\theta \in \mathbb{R}^k$ from a Dirichlet(α)
  - For the n-th word of the same document,
    * sample a topic z_n from a multinomial with parameter θ
    * sample a word w_n from a multinomial with parameter $\beta(z_n, :)$

- **Interpretation as multinomial PCA** (Buntine and Perttu, 2003)

  - Marginalizing over topic z_n, given θ, each word w_n is selected from a multinomial with parameter $\sum_{z=1}^{k} \theta_k \beta(z, :) = \beta^\top \theta$
  - Row of β = dictionary elements, θ code for a document

Probabilistic topic models and matrix factorization

- **Two different views on the same problem**

  - Interesting parallels to be made
  - Common problems to be solved

- **Structure on dictionary/decomposition coefficients** with adapted priors (Blei et al., 2004; Jenatton et al., 2010)

- **Identifiability and interpretation/evaluation of results**

- **Discriminative tasks** (Blei and McAuliffe, 2008; Lacoste-Julien et al., 2008; Mairal et al., 2009b)

- **Optimization and local minima**

  - Online learning (Mairal et al., 2009d)

Sparsifying linear methods

- **Same pattern than with kernel methods**

  – High-dimensional inference rather than non-linearities

- Main difference: in general no unique way

- Sparse CCA (Sriperumbudur et al., 2009; Hardoon and Shawe-Taylor, 2008; Archambeau and Bach, 2008)

- Sparse LDA (Moghaddam et al., 2006)

- Sparse …

Sparse methods for matrices
Summary

- Structured matrix factorization has many applications

- Algorithmic issues

  - Dealing with large datasets
  - Dealing with structured sparsity

- Theoretical issues

  - Identifiability of structures, dictionaries or codes
  - Other approaches to sparsity and structure

- Non-convex optimization versus convex optimization

  - Convexification through unbounded dictionary size (Bach et al., 2008) - few performance improvements

Sparse methods for machine learning
Outline

- **Introduction - Overview**

- **Sparse linear estimation with the ℓ_1-norm**

  – Convex optimization and algorithms
  – Theoretical results

- **Structured sparse methods on vectors**

  – Groups of features / Multiple kernel learning
  – Extensions (hierarchical or overlapping groups)

- **Sparse methods on matrices**

  – Multi-task learning
  – Matrix factorization (low-rank, sparse PCA, dictionary learning)

Links with compressed sensing
(Baraniuk, 2007; Candès and Wakin, 2008)

- Goal of compressed sensing: recover a signal $w \in \mathbb{R}^p$ from only n measurements $y = Xw \in \mathbb{R}^n$

- Assumptions: the signal is k-sparse, n much smaller than p

- Algorithm: $\min_{w \in \mathbb{R}^p} \|w\|_1$ such that $y = Xw$

- Sufficient condition on X and (k, n, p) for perfect recovery:

  - Restricted isometry property (all small submatrices of $X^\top X$ must be well-conditioned)
  - Such matrices are hard to come up with deterministically, but random ones are OK with $k \log p = O(n)$

- **Random X for machine learning?**

Sparse methods for machine learning
Why use sparse methods?

- **Sparsity as a proxy to interpretability**

  – Structured sparsity

- **Sparsity for high-dimensional inference**

  – Influence on feature design

- **Sparse methods are not limited to least-squares regression**

- **Faster training/testing**

- **Better predictive performance?**

  – Problems are sparse if you look at them the right way

Conclusion - Interesting questions/issues

- Implicit vs. explicit features

  - Can we algorithmically achieve $\log p = O(n)$ with explicit unstructured features?

- Norm design

  - What type of behavior may be obtained with sparsity-inducing norms?

- Overfitting convexity

  - Do we actually need convexity for matrix factorization problems?
