Hybrid Systems Modelers

Program complex discrete systems and their physical environments in a single language

Many tools and languages exist

- ▶ PL: Simulink/Stateflow, LabVIEW, Scicos, Ptolemy, Modelica, etc.
- ► Verif: SpaceEx, Flow*, dReal, etc.

Focus on Programming Language (PL) issues to improve safety

Our approach

- Build a hybrid modeler on top of a synchronous language
- Recycle existing techniques and tools
- Clarify underlying principles and guide language design/semantics

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

Recycle existing tools and techniques Synchronous languages (SCADE/Lustre)

- Used for critical systems design and implementation
 - mathematically sound semantics
 - certified compiler (DO178C)
- Expressive language for both discrete controllers and mode changes
- But do not support modelling of continuous-time dynamics

Off-the-shelf ODEs numeric solvers

- Sundials CVODE (LLNL) among others, treated as black boxes
- Exploit existing techniques and (variable step) solvers

A conservative extension

 Any synchronous program must be compiled, optimized, and executed as per usual

Increase confidence in the simulation code.

The Simulation Engine of Hybrid Systems

Alternate discrete steps and integration steps

$$\sigma', y' = d_{\sigma}(t, y)$$
 $upz = \frac{g_{\sigma}(t, y)}{\dot{y}} = f_{\sigma}(t, y)$

Properties of the three functions

- d_{σ} gathers all discrete changes.
- g_{σ} defines signals for zero-crossing detection.
- f_{σ} and g_{σ} should be free of side effects and, better, continuous.

Zélus, a synchronous language with ODEs [HSCC'13]

Milestones

- A synchronous non-standard semantics [JCSS'12]
- ► A Lustre language with ODEs [LCTES'11]
- Hierarchical automata, both discrete and hybrid [EMSOFT'11]
- Causality analysis [HSCC'14]; code generation [CC'15]
- A validation into the industrial KCG compiler of SCADE SCADE Hybrid at Esterel-Tech/ANSYS (2014 - 2015)
 - Prototype based on KCG 6.4 (now 6.6)
 - SCADE Hybrid = full SCADE + ODEs
 - Generates FMI 1.0 model-exchange FMUs with Simplorer

- Built from scratch.
 - Follows the organisation of the Lucid Synchrone compiler
 - Recycle and extend several type-based static analysis: typing, causality analysis, initialization analysis.
 - ► Comp. through reduction into a basic language [LCTES'08, CC'15].
- First prototype around 2011; current version is 1.2.
- Reference manual and tutorial (2015)
- ▶ 15kLOC for the compiler (Ocaml 4.02.1).
- Numeric solver: SundialsML (Ocaml binding of SUNDIALS); ODE23, ODE45.

Distribution

Information on the language (binaries, reference manual, examples):

http://zelus.di.ens.fr

Zélus source code is available on a private svn server.

svn: https://svn.di.ens.fr/svn/zelus/trunk

The SundialsML binding is available on OPAM (source code):

http://inria-parkas.github.io/sundialsml/

How Zélus behave for programming classical blocks of the Simulink standard library?

The Simulink Standard Library

Discrete Blocks

▲ロト ▲園ト ▲ヨト ▲ヨト ニヨー のへ(で)

Discrete-time blocks: the Integrator

Examples below are checked by the tool of Timothy Bourke: checklisting.sh $^{\rm 2}$

type saturation = Between | Lower | Upper

```
(* forall n in Nat.
   * [output(0) = x0(0)]
   * [output(n) = output(n-1) + (h * k) * u(n-1)] *)
  let node forward_euler(x0, k, h, u) = output where
    rec output = x0 fby (output +. (k *. h) *. u)
type saturation = | Between | Lower | Upper
val forward_euler : float * float * float * float -D-> float
  (* forall n in Nat.
   * [output(0) = x0(0)]
   * [output(n) = output(n-1) + h * u(n)] *)
  let node backward_euler(x0, k, h, u) = output where
    rec output = x0 -> pre(output) +. k *. h *. u
```

Discrete-time blocks: the Integrator (II)

```
(* forall n in Nat.
 * [output(n) = y(n)]
 * [x(0) = x0(0)]
 * [x(n) = y(n-1) + h/2 * u(n-1)]
 * [y(n) = x(n) + h/2 * u(n)] *)
 let node trapezoidal_fixed(x0, k, h, u) = output where
   rec x = x0 fby (y + . gain * . u)
   and y = x + . gain *. u
   and gain = k * h / . 2.0
   and output = y
(* Extended versions with upper/lower limits,
 * reset and output ports *)
let node forward_euler_complete(upper, lower, res, x0, k, h, u) =
   (output, state_port, saturation) where
   rec state_port = x0 fby (output +. k *. h *. u)
   and v = if res then x0 else state_port
   and (output, saturation) =
     if v < lower then lower, Lower
     else if v > upper then upper, Upper else v, Between \rightarrow \infty
```

Discrete-time PID

let node int(x0, h, u) = forward_euler(x0, 1.0, h, u)

let node derivative(h, u) = 0.0 \rightarrow (u -. pre(u)) /. h

```
(* PID controller in discrete time
 * p is the proportional gain;
 * i the integral gain;
 * d the derivative gain;
 * h is the time step *)
let node pid(p, i, d, h, u) = c where
 rec c_p = p *. u
 and i_p = int(0.0, h, i *. u)
 and c_d = derivative(h, d *. u)
 and c = c_p +. i_p +. c_d
```

Discrete-time PID (II)

```
(* The same but where initial conditions
 * are given from the arguments *)
let node pid_with_externals(p, i0, i, d, h, u) = c where
   rec c_p = p *. u
   and i_p = int(i0, h, i *. u)
   and c_d = derivative(h, d *. u)
   and c = c_p + . i_p + . c_d
(* PID with external reset *)
let node pid_with_reset(r, p, i0, i, d, h, u) = c where
  reset
    c = pid_with_externals(p, i0, i, d, h, u)
  every r
```

All other forms are programmed the same way. It is possible to add upper and lower limit.

Discrete blocks

- Most blocks can be programmed in a Lustre-like style with stream equations and a reset.
- The program is very close to the mathematical specification.
- The causality analysis, that computes the input/output relation of a node, is very helpful to understand which feebacks are possible.

Yet, Simulink provides (a lot of) features Zélus does not have: overloading of operators (+ applies to integers, floats, complex, vectors, matrices, etc.) and arrays.

- Higher order or functors would make the code more generic!
- A comparison of the generated code must be done.

Well, nothing surprising here. Several tools automatically translate a subset of Simulink discrete-time blocks into Lustre.

But is there some minimal language to define all the blocks precisely?

Continuous Blocks

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

Continuous-time Integrator

```
(* regular integration of a signal [u]
 * with initial condition [x0]*)
let hybrid int(x0, u) = x where
 rec der x = u init x0
```

```
val int : float * float -C-> float
```

```
(* integrator with zero-crossing and initial condition *)
let hybrid int_with_reset_state_port(x0, res, u) = (x, state_port)
rec der x = u init x0 reset res -> x0
and state_port = last x
```

val int_with_reset_state_port : float * zero * float -C-> float * f

Last

- last x is the previous value of x
- ▶ When x is a continous state variable, it is its left limit.
- It corresponds to the so-called state port of Simulink.

Continuous-time Integrator (II)

```
(* integrator with initial condition [x0] with threshold [lower]
* and [upper] *)
let hybrid int_limit(x0, upper, lower, u) =
 (x, state_port, saturation) where
 rec init x = x0
 and automaton
      | Between ->
        (* regular mode. Integrate the signal *)
        do der x = u and saturation = Between
        until (xup(x, upper)) then do x = upper in Upper
        else (xdown(x, lower)) then do x = lower in Lower
     | Upper ->
        (* when the speed becomes negative, go to *)
        (* the regular mode *)
        do saturation = Upper until (down(u)) then Between
      | Lower ->
         (* when positive, go to the regular mode *)
        do saturation = Lower until (up(u)) then Between
     end
 and state_port = last x
```

Continuous-time Integrator (III)

```
The same with parameterized states.
```

```
let hybrid int_limit2(x0, upper, lower, u) =
  (x, state_port, saturation) where
 rec init x = x0
 and automaton
      | Between ->
          (* regular mode. Integrate the signal *)
          do der x = u and saturation = Between
          until (xup(x, upper)) then do x = upper in Bound(false)
          else (xdown(x, lower)) then do x = lower in Bound(true)
      | Bound(right) ->
          (* when the speed becomes negative, go to the *)
          (* regular mode *)
          do saturation = if right then Lower else Upper
          until (up(if right then u else -. u)) then Between
      end
 and state_port = last x
```

Continuous-time Integrator (IV)

Continuous-time PID

```
(* Derivative. Applied on a linear filtering of the input
* n is the filter coef. [n = inf] would mean no filtering.
 * transfer function is [N s / (s + N)] *)
let hybrid derivative(n, f0, u) = udot where
 rec udot = n * . (u - . f)
 and der f = udot init f0
let hybrid int(x0, u) = x where
 rec der x = u init x0
(* PID controller in continuous time
 * p is the proportional gain;
 * i the integral gain;
 * d the derivative gain;
 * N the filter coefficient *)
let hybrid pid(p, i, d, n, u) = c where
  rec c_p = p *. u
   and i_p = int(0.0, i *. u)
   and c_d = derivative(n, 0.0, d *. u)
   and c = c_p + . i_p + . c_d
```

Continuous-time PID (II)

```
(* The same but where initial conditions are given from
 * the arguments *)
let hybrid pid_with_externals(p, i0, f0, i, d, n, u) = c where
  rec c_p = p *. u
  and i_p = int(0.0, i *. u)
   and c_d = derivative(n, f0, d *. u)
   and c = c_p + . i_p + . c_d
(* PID with external reset *)
let hybrid pid_with_reset(r, p, i0, f0, i, d, n, u) = c where
 reset
   c = pid_with_externals(p, i0, f0, i, d, n, u)
 every r
```

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Continuous-time blocks

The programming style is similar than that for discrete-time blocks.

- > The dependence-based causality analysis extends directly to ODEs:
 - An equation der x = ...x... init x0 is like x = x0 fby (...x...) in data-flow: x does not depend on itself.
 - E.g., der x = 1.0 .x init 0.0 is causally correct.
 - E.g., der x = 1.0 init 0.0 reset $z \rightarrow 0.2 *. x$ is not.
 - last x must be used to break causality loops.
- Same weaknesses as before: no overloading, arrays, etc.
- Again, high-order would make the code more generic.
- Yet, current typing constraints that forbid the use of comparison operators during integration is a burden.

Discontinuous Blocks

▲□ > ▲□ > ▲ 三 > ▲ 三 > ● ④ < ④

Rising, falling, either

```
(* Hit crossing *)
let hybrid rising(input, offset) = up(input -. offset)
```

let hybrid falling(input, offset) = up(-. input +. offset)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

```
val rising : float * float -C-> zero
val falling : float * float -C-> zero
val positive : float -C-> bool
```

Rising, falling, either

```
let hybrid either(eps, input, offset) = ok where
  rec automaton
        | AtCrossing ->
           do ok = true
           unless (up(input -. (offset +. eps))) then Higher
           else (up(-. (input -. (offset -. eps)))) then Lower
        | Higher ->
           do ok = false
           unless (up(-. (input +. offset))) then AtCrossing
        | Lower ->
           do ok = false
           unless (up(input -. offset)) then AtCrossing
        end
val either : float * float * float -C-> bool
```

Either (II)

```
ok = true when abs(x − v) ≤ ϵ
let hybrid either_abs(eps, x, v) = ok where
  rec o = abs_float(x −. v) −. eps and ok = positive(o)
val either_abs : float * float * float -C-> bool
Difficulty
```

- up(e) only detect that e crosses zero, i.e., from strictly negative to strictly positive.
- It does not detect that a signal sticked to zero then leaves zero.
- Adding ϵ (as we do), with or without an hysteresis is not satisfactory.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

The problem is not simple at all!

The Backlash

Three modes (Simulink's specification)

- Disengaged: "In this mode, the input does not drive the output and the output remains constant."
- Engaged in a positive direction: "In this mode, the input is increasing (has a positive slope) and the output is equal to the input minus half the deadband width."

Engaged in a negative direction: "In this mode, the input is decreasing (has a negative slope) and the output is equal to the input plus half the deadband width"

Difficulty

- Detect the change in sign of the derivative.
- But Zélus does not provide the derivative of a signal.

The Backlash

Approximate the derivative, either by sampling or a linear filter.

```
let hybrid backlash (width, y0, u) = y where
  rec half = width /. 2.0
   and init y = y0
   and automaton
       | Disengaged ->
          do unless (up(u -. (last y +. half)))
          then Engaged_positive
          else (up(-. (u -. (last y -. half))))
          then Engaged_negative
       | Engaged_positive ->
          do y = u - . half
          unless (up(-. derivative(u))) then Disengaged
       | Engaged_negative ->
          do y = u + . half
          unless (up(derivative(u))) then Disengaged
       end
```

Modeling a second order system with saturation See: http://blogs.mathworks.com/seth/2014/01/22/ how-to-model-a-hard-stop-in-simulink/

Example: clutch control DEMO

The Zélus typing discipline

- All discontinuities are aligned with a zero-crossing.
- Checked during static typing.
- In particular, values with a discrete type (e.g., bool, int) do not change during integration.

Discrete events

A zero-crossing up(e) returns a value of type zero.

It can be used to trigger a regular Lustre node.

Separation between Discrete and Continuous Time The type language [LCTES'11]

Function Definition: fun f(x1,...) = (y1,...)

• Combinatorial functions (A); usable anywhere.

Node Definition: node f(x1,...) = (y1,...)

Discrete-time constructs (D) of SCADE/Lustre: pre, ->, fby.

Hybrid Definition: hybrid f(x1,...) = (y1,...)

Continuous-time constructs (C): der x = ..., up, down, etc.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

An excerpt of the Pervasives module from Zélus AD for discrete stateless functions (A < AD < D).

```
val ( = ) : 'a * 'a -AD-> bool
val ( <> ) : 'a * 'a -AD-> bool
val (\langle \rangle) : 'a * 'a -AD-> bool
val ( > ) : 'a * 'a -AD-> bool
val ( <= ) : 'a * 'a -AD-> bool
val ( >= ) : 'a * 'a -AD-> bool
val min : 'a * 'a -A-> 'a
val not : bool -A \rightarrow bool
val (\&) : bool * bool -A-> bool
val (or) : bool * bool -A \rightarrow bool
val up : float -C-> zero
val disc : 'a -C \rightarrow Zero
val ( on ) : zero * bool -> zero
val orz : zero * zero -> zero
```

. . .

A program that is rejected

```
let hybrid wrong(x, y) = x \ge y
```

Zélus prevents from writting a boolean signal that may change during integration, even if it is not used.

Zélus vs SCADE Hybrid

. . .

SCADE Hybrid is less constraining: Only state changes must be aligned on a zero-crossing. But, the argument of an up(.) must be "smooth" (C^{∞}).

The separation between continous-time and discrete-time is done during the **clock calculus**.

It is possible to write comparisons and signals that are discontinuous during integration, whereas Zélus forbids, e.g.:

if $x \ge$ high then high else if $x \le$ low then low else x

der x = if $x \ge 0.0$ then -1.0 else 1.0 init 0.0

An extra type system indicates whether a signal is piece-wise constant, smooth or (possibly) discontinuous between two zero-crossings.

Current work

Write other blocks from the standard Simulink library; write complete examples to exercice the compiler.

- Examples: Backhoe, Bang bang controller, clutch model, etc.
- These experiments exercice all features of the languages.
- Zélus imposes a change in programming style w.r.t Simulink.
- Zélus reject programs that are accepted by Simulink.
- E.g., current typing constraints of Zélus forbids the use of comparisons during integration (if x >= 0.0 then ... is forbidden). Use boolean operations instead (if x then ... is valid).

This is preliminary work: compare efficiency, accuracy, style, in detail.

Some problems we faced (I)

Causality analysis

An output should not depend on a condition when it weak. Zélus is too constraining, making the output depending on the condition. In comparison, SCADE Hybrid does better.

Typing discrete/continuous blocks

- We may have been overly constraining as solvers manage discontinuous signals. Yet, results may be weird.
- ► SCADE Hybrid is more permissive. It is possible to write der x = if x >= 0 then -1.0 else 1.0 but impose that e be smooth in up(e).
- More experiments to be done. An idea is to associate the kind to type variables. E.g.,:

```
val (=) : Discrete('a). 'a * 'a -A-> bool
```

or use an extra type system as in SCADE Hybrid.

What is the minimal mathematical and executable language we need to define all the blocks, with a description not longer than the Simulink documentation?

Extensions

- Translate ODEs into difference equations (synchronous code) for real-time simulation.
- The derivative of a signal is not provided. Should we provide automatic differentiation or an internal implementation that give an approximated value (e.g., as Simulink does)?
- Arrays. SCADE Hybrid have them; Implementation in Zélus is under way with a form of iterator inspired by SISAL.

Verification

 Translate programs into a basic Lustre-like language with ODEs, used as an input for formal verification.

Compiler

Zélus is a synchronous language extended with Ordinary Differential Equations (ODEs) to model systems with complex interaction between discrete-time and continuous-time dynamics. It shares the basic principles of Lustre with features from Lucid Synchrone (type inference, hierarchical automata, and signals). The compiler is written

Research

Zélus is used to experiment with new techniques for building hybrid modelers like Simulink/Stateflow and Modelica on top of a synchronous language. The language exploits novel techniques for defining the semantics of hybrid modelers, it provides dedicated type systems to ensure the absence of discontinuities during integration and the
