#### Abstract

In this paper we settle a logical semantics for the class CC of concurrent constraint programming languages and for its extension LCC based on linear constraint systems. Besides the characterization in intuitionistic logic of the stores of CC computations, we show that both the stores and the successes of LCC computations can be characterized in intuitionistic linear logic. We illustrate the usefulness of these results by showing with examples how the phase semantics of linear logic can be used to give simple "semantical" proofs of safety properties of LCC programs<sup>1</sup>.

#### 1 Introduction

Constraint programming is an emerging technology that has been proved very successful for complex system modeling and for solving declaratively combinatorial search problems [14]. The class  $CLP(\mathcal{X})$  of constraint logic programming languages, introduced by Jaffar and Lassez [13], extends logic programming by combining the pure Horn fragment of first-order logic (FOL) for defining relations, with a fixed decidable FOL language of primitive constraints over some structure  $\mathcal{X}$ . The logical semantics of logic programming for both successes and finite failures extend smoothly to CLP languages, by considering the consequences in classical logic of both the program and the theory of the structure  $th(\mathcal{X})$ . This is achieved in pure CLP for various observable properties of the execution: the existence of a successful derivation to a query [13], the set of computed answer constraints [21, 8], finite failures [13], the set of computed constraints with constructive negation [33, 6], etc. For example, computed answer constraints (i.e. final states of computations) can be observed logically: any computed constraints entails the initial goal (modulo the logical translation of the program  $P^{\star}$  and the constraint system  $\mathcal{C}$ ); conversely any constraint c entailing a goal G is covered (again modulo  $P^*$  and  $\mathcal{C}$ ) by a finite set of computed constraints  $c_1 \ldots c_n$ , i.e.  $\mathcal{C} \vdash \forall (c_1 \ldots c_n \Rightarrow c)$ . This allows for powerful analysis methods and simple program transformation techniques based on logical equivalences.

The class  $CC(\mathcal{X})$  of *Concurrent Constraint* programming languages introduced by Saraswat [29] in 1987 arised as a natural combination of constraint logic programming and concurrent logic programming, with the introduction of a synchronization mechanism based on constraint entailment [21]. CC programming is a model of concurrent computation, where agents communicate through a shared store, represented by a constraint, which expresses some *partial information* on the values of the variables involved in the computation. An agent may add information c to the store (agent tell(c)), or ask the store to entail a given constraint ( $c \rightarrow A$ ). Communication is *asynchronous*: agents can remain idle, and senders (constraints c) are not blocking. The synchronization mechanism of CC languages gives an account for the co-routining facilities of implemented CLP systems, like the freeze predicate of Prolog, the delay mechanism of  $\text{CLP}(\mathcal{R})$  [13], or the constraint propagation schemes of CLP(FD). It also opens, to some extent, constraint programming to a new field of applications which are traditional in concurrent programming, like reactive systems and protocol specifications.

From the logic programming tradition however, the operational aspects of CC programming should also be closely connected to a logical semantics for reasoning about programs at different levels of abstraction, getting rid of useless details of the execution. The monotonic evolution of the store during CC computations provides CC languages with a simple denotational semantics in which agents are identified to closure operators on the semi-lattice of constraints [32, 15]. Such denotational semantics are used in [5] to obtain a complete calculus for partial correctness assertions where the rules of the proof system mirror the equations of the denotational semantics.

In this article, we explore another route based on Girard's intuitionistic linear logic (ILL) [10]. We review the semantics of CC languages in the logic programming paradigm based on linear logic and we investigate the use of the phase semantics for proving safety properties of CC programs.

#### Outline of the paper.

Section 2 presents a natural extension of CC languages in this context, namely Linear CC (LCC) where the constraint system is axiomatized in linear logic. LCC is an extension of CC, somewhat similar to [3] or [30], but where constraints are *consumed* by ask agents without dependency maintenance or recomputation. Linear constraint systems have also been proposed in [31] in a higher-order setting which will not be considered here. From an operational point of view, LCC extends CC in a fundamental way by introducing some forms of imperative programming, particularly useful for reactive systems. Classical CC programs can however be recovered by the usual translation of intuitionistic logic into linear logic [10].

Section 3 settles the basic soundness and completeness results of CC and LCC operational semantics w.r.t. intuitionistic linear logic. Results similar to those of this section are part of the folklore on CC languages [19, 31] but have not been published. Here we prove that 1) the stores of CC computations can be characterized in intuitionistic logic, and 2) both the stores and the successes of CC and LCC computations can be characterized in intuitionistic logic. Completeness results show that ILL can be used to prove *liveness properties* of LCC programs, i.e. properties expressing that something good will eventually happen. This is developed for both "may" and "must" properties.

Then we show in section 4.2 how *safety properties* of CC and LCC programs (i.e. that some derivations never happen) can be proved using the phase semantics of linear logic. The method relies on the soundness theorem of LCC computations w.r.t. linear logic, and on the soundness theorem of linear logic w.r.t. the phase semantics. Completeness results simply say in this context that for various classes of observable properties of the program, if the property holds then such a "phase semantical proof" exists. The method is illustrated with

several examples of LCC programs for protocol specifications.

#### Related work.

The connection between CC languages and linear logic is based on the logic programming paradigm in a broad sense, that identifies programs-as-formulas and execution-as-proof-search. This paradigm was applied to linear logic with the notion of uniform proofs [22, 12] and focusing proofs [1], and further works on the design of concurrent languages based on proof search in LL [16, 25].

However our approach is analytical in that we study an existing programming language CC, and model CC computations in a fragment of LL. On the other hand we model properties of infinite CC computations through the observation of accessible stores which has no counterpart in the uniform proofs approach. Therefore both series of results are quite different.

Recently, phase semantics has gained interest in its applications to cut elimination [24], complexity of provability and decidability [17] (see [18] for a survey). Section 4.2 presents a new field of application of the phase semantics, yet unexplored though quite natural in the paradigm of concurrent logic programming.

#### 2 CC operational semantics

#### 2.1 CC

**Definition 2.1 (Intuitionistic constraint system)** A constraint system is a pair  $(\mathcal{C}, \vdash_{\mathcal{C}})$ , where:

- C is a set of formulas (the constraints) built from a set V of variables, a set Σ of function and relation symbols, with logical operators: 1 (true), the conjunction ∧ and the existential quantifier ∃;
- $\vdash_{\mathcal{C}}$  is the least subset of  $\mathcal{C}^* \times \mathcal{C}$  containing  $\Vdash_{\mathcal{C}}$  and closed by the rules of intuitionistic logic (IL) for 1,  $\land$  and  $\exists$  (fv(A) denotes the set of free variables occurring in A):

$$\begin{array}{cccc} \Gamma, c \vdash c & \frac{\Gamma, c \vdash d & \Gamma \vdash c}{\Gamma \vdash d} & \vdash 1 & \frac{\Gamma \vdash c}{\Gamma, 1 \vdash c} \\ \\ \hline \Gamma, d, d \vdash c & \frac{\Gamma \vdash c}{\Gamma, d \vdash c} & \frac{\Gamma \vdash c}{\Gamma \vdash \exists xc} & \frac{\Gamma, c \vdash d}{\Gamma, \exists xc \vdash d} x \not\in fv(\Gamma, d) \\ \\ \hline \frac{\Gamma \vdash c_1 & \Gamma \vdash c_2}{\Gamma \vdash c_1 \land c_2} & \frac{\Gamma, c_1 \vdash c}{\Gamma, c_1 \land c_2 \vdash c} & \frac{\Gamma, c_2 \vdash c}{\Gamma, c_1 \land c_2 \vdash c} \end{array}$$

In the following,  $c, d, e \dots$  will denote constraints. Note that the intuitionistic logical framework (rather than the classical one) is not essential, it is simply sufficient, taking into account that the constraints are only built from conjunctions and existential quantifications. **Definition 2.2 (Agents)** The syntax of CC agents is given by the following grammar:

$$A ::= p(\vec{x}) \mid tell(c) \mid (A \parallel A) \mid A + A \mid \exists xA \mid \forall \vec{x}(c \to A)$$

where  $\parallel$  stands for parallel composition, + for non-deterministic choice,  $\exists$  for variable hiding and  $\rightarrow$  for blocking ask. The atomic agents  $p(\vec{x}) \dots$  are called process names or procedure names.

Classically, the *ask* agents are not written with a universal quantifier [29]. The reason is that in the Herbrand domain, a  $CC(\mathcal{H})$  ask agent, like for example  $\forall y, z(x = [y, z] \rightarrow A(x, y, z))$  for decomposing a list, can be written without universal quantifier, by duplicating the constraint in the guard and in the body of the *ask*:  $(\exists y, z \ x = [y|z]) \rightarrow (tell(x = [y|z]) \parallel A(x, y, z))$ . This programming trick is rather cumbersome however and does not generalize to every constraint domains nor to linear constraint systems. Therefore we shall not adopt it in this paper, and we shall make explicit the universal quantification of variables in *ask* agents.

Recursion is obtained by declarations:

**Definition 2.3 (Declarations)** The syntax of declarations is given by the following grammar:

$$D ::= \epsilon \mid p(\vec{x}) = A \mid D, D$$

The set of declarations of a CC program is denoted by  $\mathcal{D}$ .

**Definition 2.4 (Programs)** A program D.A is a declaration D together with an agent A.

We make the very natural hypothesis that in a declaration  $p(\vec{x}) = A$ , all the free variables occurring in A occur in  $\vec{x}$ , and that in a relation  $c_1 \ldots c_n \Vdash_{\mathcal{C}} c$ , all the free variables occurring in c have a free occurrence in  $c_1 \ldots c_n$ . Notice that this is exactly the meaning associated with the Horn clauses in the logic programming languages, for instance: the variables which are free in the body but not in the head are considered (implicitly in the syntax, explicitly in the semantics) as existentially quantified in the body (because universally in the clause).

The operational semantics is defined on configurations (rather than agents) where the store is distinguished from agents:

**Definition 2.5 (Configurations)** A configuration is a triple  $(\vec{x}; c; \Gamma)$ , where  $\vec{x}$  is a set of variables, c is a constraint, and  $\Gamma$  a multiset of agents.

In a configuration  $(\vec{x}; c; \Gamma)$ ,  $\vec{x}$  denotes the set of *hidden* variables and c is the store. Let  $\mathcal{A}$  (resp.  $\mathcal{B}$ ) denotes the set of agents (resp. configurations). The operational semantics is defined by a transition system which does not take into account specific evaluation strategies. The transitions system is given in the style of the CHAM [2] (see also [26]). We distinguish a congruence relation (between configurations) from the very transition relation (between configurations): **Definition 2.6 (Transitions)** The structural congruence  $\equiv$  is the least congruence satisfying the rules of table 1.

lpha-Conversion	$\frac{z \notin v(A)}{\exists y A \equiv \exists z A[z/y]}$
Parallel composition	$(\vec{x};c;A\parallel B,\Gamma)\equiv(\vec{x};c;A,B,\Gamma)$
Hiding	$\frac{y \not\in \vec{x} \cup fv(c, \Gamma)}{(\vec{x}; c; \exists yA, \Gamma) \equiv (\vec{x}, y; c; A, \Gamma)} \ \frac{y \not\in fv(c, \Gamma)}{(\vec{x}, y; c; \Gamma) \equiv (\vec{x}; c; \Gamma)}$

Table 1: Structural congruence

The transition relation  $\longrightarrow_{CC}$  is the least transitive relation on configurations satisfying the rules of table 2.

Tell	$(\vec{x};c;tell(d),\Gamma) \longrightarrow_{CC} (\vec{x};c \wedge d;\Gamma)$				
Ask	$\frac{c \vdash_{\mathcal{C}} d[\vec{t}/\vec{y}]}{(\vec{x};c;\forall \vec{y}(d \to A), \Gamma)  _{CC} (\vec{x};c;A[\vec{t}/\vec{y}], \Gamma)}$				
Procedure calls	$\frac{(p(\vec{y}) = A) \in P}{(\vec{x}; c; p(\vec{y}), \Gamma) \longrightarrow_{CC} (\vec{x}; c; A, \Gamma)}$				
=	$\frac{(\vec{x};c;\Gamma) \equiv (\vec{x}';c';\Gamma') \longrightarrow_{CC} (\vec{y}';d';\Delta') \equiv (\vec{y};d;\Delta)}{(\vec{x};c;\Gamma) \longrightarrow_{CC} (\vec{y};d;\Delta)}$				
Blind choice	$ \begin{array}{l} (\vec{x};c;A+B,\Gamma) \longrightarrow_{CC} (\vec{x};c;A,\Gamma) \\ (\vec{x};c;A+B,\Gamma) \longrightarrow_{CC} (\vec{x};c;B,\Gamma) \end{array} $				

Table 2: CC transition relation

where  $\phi[\vec{t}/\vec{x}]$  denotes the formula  $\phi$  in which variables  $\vec{x}$  have been replaced by terms  $\vec{t}$ .

The reflexive closure of  $\longrightarrow_{CC}$  is denoted by  $\longrightarrow_{CC}^*$ .

CC programs are parameterized by a constraint system. In general the constraint system C will be implicit in our presentation, both in the transition system and the constraint entailment. Similarly the set of declarations D will be kept implicit.

The agents and declarations without + are said *deterministic*. This name is justified by the following proposition:

**Proposition 2.7 (Confluence [32])** For any deterministic configuration  $\kappa$ with deterministic declarations, if  $\kappa \longrightarrow_{CC} \kappa_1$  and  $\kappa \longrightarrow_{CC} \kappa_2$ , then there exists a deterministic configuration  $\kappa'$  such that  $\kappa_1 \longrightarrow_{CC} \kappa'$  and  $\kappa_2 \longrightarrow_{CC} \kappa'$ .

Another property of CC programs is that the execution is *extensive* and *monotonic*:

**Proposition 2.8 (Extensivity [32])** If  $(\vec{x}; c; \Gamma) \longrightarrow_{CC} (\vec{y}; d; \Delta)$  then  $\exists \vec{y} d \vdash_{\mathcal{C}} \exists \vec{x} c$ .

#### Proposition 2.9 (Monotonicity [32])

If  $(\vec{x}; c; \Gamma) \longrightarrow_{CC} (\vec{y}; d; \Delta)$ , then for every multiset of agents  $\Sigma$  and every constraint  $e, (\vec{x}; c \land e; \Gamma, \Sigma) \longrightarrow_{CC} (\vec{y}; d \land e; \Delta, \Sigma)$ .

As usual, the precise operational semantics depends on the choice of observables. We shall consider stores, successes and suspensions:

**Definition 2.10 (Observables)** The store of a configuration  $(\vec{x}; c; \Gamma)$  is the constraint  $\exists \vec{x}c$ . We will say that  $\exists \vec{x}d$  is an accessible store from the agent A and the initial store c, if there exists a multiset of formulas  $\Gamma$  such that  $(\emptyset; c; A) \longrightarrow_{CC}^{*} (\vec{x}; d; \Gamma)$ .

A success store (resp. a success) for an agent A and an initial store c is a constraint  $\exists \vec{x}d$  (resp. a configuration  $(\vec{x}; d; \emptyset)$ ) such that  $(\emptyset; c; A) \longrightarrow_{CC}^{*} (\vec{x}; d; \emptyset)$ .

A suspension for A and initial store c is a configuration  $(\vec{x}; d; d_1 \rightarrow A_1, \ldots, d_n \rightarrow A_n)$  such that  $n \ge 0$ ,  $(\emptyset; c; A) \xrightarrow{*}_{CC} (\vec{x}; d; d_1 \rightarrow A_1, \ldots, d_n \rightarrow A_n)$  and for no  $i, d \vdash_{C} d_i$ .

It is easy to see that, by the monotonicity and extensivity properties of CC programs, the operational behavior of CC programs under these observables is completely characterized by their behavior on agents with an empty initial store. Namely the accessible stores from A with initial store c are the conjunctions of c and of the accessible stores from  $A \parallel (tell \ c)$  with the empty initial store (prop. 2.9), the success stores from A with c are the success stores of  $A \parallel tell(c)$  with the empty initial store, and similarly for suspensions. Therefore the operational semantics can be defined by:

#### Definition 2.11 (Operational semantics)

 $\mathcal{O}_{CC}^{store}(\mathcal{D}.A) = \{ \exists \vec{x} d \in \mathcal{C} \mid (\emptyset; 1; A) \longrightarrow_{C}^{*} (\vec{x}; d; \Gamma) \} \\ \mathcal{O}_{CC}^{term}(\mathcal{D}.A) = \{ \exists \vec{x} d \in \mathcal{C} \mid (\emptyset; 1; A) \longrightarrow_{C}^{*} (\vec{x}; d; \Gamma) \not\longrightarrow_{CC} \} \\ \mathcal{O}_{CC}^{success}(\mathcal{D}.A) = \{ \exists \vec{x} d \in \mathcal{C} \mid (\emptyset; 1; A) \longrightarrow_{C}^{*} (\vec{x}; d; \emptyset) \}$ 

#### Remark on non-determinism.

In the transition system, we have adopted the *blind-choice* rule: the nondeterministic agent A + B can behave either like A or like B. Replacing the blind choice rule (also called "internal choice") by the rules for the *one-step* guarded choice (also called "external choice"):

$$\frac{(\vec{x};c;A,\Gamma) \longrightarrow_{CC} (\vec{y};d;\Delta)}{(\vec{x};c;A+B,\Gamma) \longrightarrow_{CC} (\vec{y};d;\Delta)} \text{ and } \frac{(\vec{x};c;B,\Gamma) \longrightarrow_{CC} (\vec{y};d;\Delta)}{(\vec{x};c;A+B,\Gamma) \longrightarrow_{CC} (\vec{y};d;\Delta)}$$

would obviously change the suspensions of a program. For instance, let  $\kappa = (\emptyset; c; (c \to tell(1)) + (d \to tell(1)))$  with  $c \not\vdash_C d$ , then for the blind choice,  $\kappa$  has two possible derivations:  $\kappa \longrightarrow_{CC} (\emptyset; c; c \to tell(1)) \longrightarrow_{CC} (\emptyset; c; tell(1)) \longrightarrow_{CC} (\emptyset; c; \emptyset)$  and  $\kappa \longrightarrow_{CC} (\emptyset; c; d \to tell(1)) \not\rightarrowtail_{CC}$ , whereas the second derivation is not accepted by the one-step choice. It is worth noting however that the set of successes, as well as the set of accessible stores remain the same under both interpretations. For the sake of simplicity we have not explicitly treated here all forms of non-determinism, but the results presented in this paper remain valid as long as only accessible stores and successes are observed.

**Proposition 2.12** Let  $\mathcal{O}_{CC'}^{store}$  and  $\mathcal{O}_{CC'}^{success}$  denote the operational semantics defined above with the one-step guarded choice rules instead of the blind choice rules. Let A be a CC agent, we have:  $\mathcal{O}_{CC}^{store}(\mathcal{D}.A) = \mathcal{O}_{CC'}^{store}(\mathcal{D}.A)$  and  $\mathcal{O}_{CC}^{success}(\mathcal{D}.A) = \mathcal{O}_{CC'}^{success}(\mathcal{D}.A)$ 

**Proof.** Obvious induction: let  $-\to_{CC'}$  be the transition relation with the one-step guarded choice rules, consider a  $-\to_{CC}$  derivation, it diverges from a  $-\to_{CC'}$  derivation when it stops after a transition with the blind choice rule, but then: 1) the observed store has not changed, and 2) the terminal configuration is not a success.

The monotonicity and extensivity properties provide CC with a denotational semantics, where the agents are seen as closure operators on the semi-lattice of constraints [32, 15]. In this paper however, we shall also be concerned with a variant of CC languages where constraints are formulas in linear logic [10] and where extensivity is dropped.

#### 2.2 Linear CC

Roughly speaking, there are two reasons to consider linear constraints:

- on one hand, as we shall see in section 3.2, linear logic enables the characterization of finer observables than intuitionistic logic, and is therefore a natural semantics for CC;

- on the other hand, variants of CC, where the constraints can be consumed by ask agents and thus removed from the store, have been introduced by Saraswat and Lincoln [31], then further studied in [3, 34]: these variants enhance significantly the expressive power of CC (see the examples of communication protocol programs in section 2.2.3) and the constraints are naturally modeled as formulas of linear logic.

In this section we present such a version, LCC, and give a translation from CC into LCC respecting the transition system, so that LCC is a refinement of CC, and the logical characterization that we will make on the operational behavior of LCC is also correct for CC.

#### 2.2.1 Syntax

As for CC, we define the constraint systems, the agents, the configurations and the transition system. The essential difference with CC is that constraints are formulas of linear logic and that communication (the ask rule) consumes information.

**Definition 2.13 (Linear constraint system)** A linear constraint system is a pair  $(\mathcal{C}, \vdash_{\mathcal{C}})$ , where:

- C is a set of formulas (the linear constraints) built from a set V of variables, a set Σ of function and relation symbols, with logical operators: the multiplicative conjunction ⊗, its neutral element 1, the existential quantifier ∃ and the exponential connective !;
- $\Vdash_{\mathcal{C}}$  is a subset of  $\mathcal{C} \times \mathcal{C}$  which defines the non-logical axioms of the constraint system.
- $\vdash_{\mathcal{C}}$  is the least subset of  $\mathcal{C}^* \times \mathcal{C}$  containing  $\Vdash_{\mathcal{C}}$  and closed by the following rules (fv(A) denotes the set of free variables occurring in A):

$$c \vdash c \qquad \frac{\Gamma, c \vdash d}{\Gamma, \Delta \vdash d} \qquad \vdash 1 \qquad \frac{\Gamma \vdash c}{\Gamma, 1 \vdash c}$$

$$\frac{\Gamma, c_1, c_2 \vdash c}{\Gamma, c_1 \otimes c_2 \vdash c} \qquad \frac{\Gamma \vdash c_1}{\Gamma, \Delta \vdash c_1 \otimes c_2} \qquad \frac{\Gamma \vdash c}{\Gamma \vdash \exists xc} \qquad \frac{\Gamma, c \vdash d}{\Gamma, \exists xc \vdash d} \quad x \notin fv(\Gamma, d)$$

$$\frac{\Gamma, c \vdash d}{\Gamma, !c \vdash d} \qquad \frac{!\Gamma \vdash d}{!\Gamma \vdash !d} \qquad \frac{\Gamma \vdash d}{\Gamma, !c \vdash d} \qquad \frac{\Gamma, !c, !c \vdash d}{\Gamma, !c \vdash d}$$

These are the rules of intuitionistic linear logic (ILL) for  $1, \otimes, \exists$  and ! (see appendix A).

Note that the intuitionistic constraint systems of the previous section can be recovered by writing all constraints under a !, as in the usual translation of intuitionistic logic into linear logic [10]. We have chosen to limitate the use of ! to constraints only, because the usual replication operator of process calculi (like the  $\pi$ -calculus [23], where it is also noted !) does not have the same behavior as the exponential connective: it allows replication ( $!A \longrightarrow_{LCC} (!A \parallel !A)$ ) but not erasing ( $!A \not \longrightarrow_{LCC} \emptyset$ ).

In general, linear constraints are not erasable in the sense that  $d \not\vdash 1$ . One defines the following *subsumption* preorder between linear constraints:

**Definition 2.14** The subsumption preorder > is defined by: c > d iff  $c \vdash_{\mathcal{C}} d \otimes \top$ .

Recall that  $\top$  is the "true" connective of linear logic (see appendix A): therefore c > d iff there exists a formula A s.t.  $c \vdash_{\mathcal{C}} d \otimes A$ .

The definition of LCC *agents*, *declarations* and *configurations* is the same as in CC (section 2.1), and we assume again very naturally that in a declaration  $p(\vec{x}) = A$ , all the free variables occurring in A have a free occurrence in p, and that in a relation  $c_1 \ldots c_n \Vdash_{\mathcal{C}} c$ , all the free variables occurring in c have a free occurrence in  $c_1 \ldots c_n$ .

**Definition 2.15** The structural congruence  $\equiv$  is the same as for CC (Definition 2.6). The transition relation  $\longrightarrow_{LCC}$  is defined by the same rules as for CC (Definition 2.6), except for LinearTell and LinearAsk:

 $\begin{array}{ll} \mathbf{LinearTell} & (\vec{x};c;tell(d),\Gamma) \longrightarrow_{LCC} (\vec{x};c\otimes d;\Gamma) \\ \\ \mathbf{LinearAsk} & \frac{c\vdash_{\mathcal{C}} d\otimes e[\vec{t}/\vec{y}]}{(\vec{x};c;\forall\vec{y}(e\rightarrow A),\Gamma) \longrightarrow_{LCC} (\vec{x};d;A[\vec{t}/\vec{y}],\Gamma)} \end{array}$ 

The calculus is intrinsically non-deterministic, even without the choice operator +, since several constraints can satisfy the condition of the rule. Of particular interest in this context are the *synchronization constraints* which are linear atomic constraints without entailment. An *ask* with a synchronization constraint is thus deterministic. We shall see examples of this in section 2.2.3 with communication protocol programs.

Because constraints are linear formulas, we must slightly modify the definition of suspensions.

#### **Definition 2.16 (Observables)** The successes are defined as in CC.

A store accessible from A and the initial store c is a constraint e such that there exist a constraint d and a multiset  $\Gamma$  of agents such that  $(\emptyset; c; A) \longrightarrow_{LCC} (\emptyset; d; \Gamma)$  and d > e.

A suspension for A with initial store c is a configuration  $(\vec{x}; d; d_1 \rightarrow A_1, ..., d_n \rightarrow A_n)$  such that  $n \ge 0$ ,  $(\emptyset; c; A) \longrightarrow_{LCC} (\vec{x}; d; d_1 \rightarrow A_1, ..., d_n \rightarrow A_n)$  and for no i,  $d > d_i$ .

An agent A with initial store c suspends with the store d on the constraints  $d_1, ..., d_n$ , if there exist a suspension for A and c of the form  $(\vec{x}; d; d_1 \rightarrow A_1, ..., d_n \rightarrow A_n)$ .

It is worth noting that the monotonicity property is still preserved in LCC:

#### Proposition 2.17 (Monotonicity)

If  $(\vec{x}; c; \Gamma) \longrightarrow_{LCC} (\vec{y}; d; \Delta)$ , then for every multiset of agents  $\Sigma$  and every constraint  $e, (\vec{x}; c \otimes e; \Gamma, \Sigma) \longrightarrow_{LCC} (\vec{y}; d \otimes e; \Delta, \Sigma)$ .

Similarly to the previous section, the observable properties of LCC computations from an empty initial store suffice to recover the properties of LCC computations from a non-empty initial store. The argument is the same for the observation of successes and terminal stores, but is somewhat more tricky for the observation of accessible stores<sup>2</sup>.

#### Definition 2.18 (Operational semantics)

 $\mathcal{O}_{LCC}^{store}(\mathcal{D}.A) = \{\exists \vec{x}d \in \mathcal{C} \mid (\emptyset; 1; A) \longrightarrow_{LCC}^{*} (\vec{x}; d; \Gamma)\} \\ \mathcal{O}_{LCC}^{term}(\mathcal{D}.A) = \{\exists \vec{x}d \in \mathcal{C} \mid (\emptyset; 1; A) \longrightarrow_{LCC}^{*} (\vec{x}; d; \Gamma) \not \longrightarrow_{LCC}\} \\ \mathcal{O}_{LCC}^{success}(\mathcal{D}.A) = \{\exists \vec{x}d \in \mathcal{C} \mid (\emptyset; 1; A) \longrightarrow_{LCC}^{*} (\vec{x}; d; \emptyset)\}$ 

**Proposition 2.19** The set of accessible stores from a configuration  $(\emptyset; c; A)$  is the set of constraints e such that  $(e \otimes d) \in \mathcal{O}_{LCC}^{store}(\mathcal{D}.(tell(c \otimes d \otimes d) \parallel (d \rightarrow A)) \setminus \{c \otimes d \otimes d\}$ , where d is a new constraint token not appearing in the constraint system.

**Proof.** As d is a new constraint token, the only possible transitions are:

 $\begin{array}{c} (\emptyset; 1; tell(c \otimes d \otimes d) \parallel (d \to A)) \\ \longrightarrow_{LCC} (\emptyset; c \otimes d \otimes d; d \to A) \end{array}$ 

 $\longrightarrow_{LCC} (\emptyset; c \otimes d; A) \longrightarrow_{LCC} \cdots$ 

Therefore the accessible stores from  $(\emptyset; c; A)$  are the accessible stores from  $(\emptyset; 1; tell(c \otimes d \otimes d) \parallel (d \to A))$  except 1 and  $c \otimes d \otimes d$  which correspond to the first two configurations, and where d is removed.

#### 2.2.2 Translation from CC to LCC

The LCC languages are a refinement of usual CC languages. Indeed the extensivity of CC can simply be restored with the exponential connective ! of linear logic, allowing replication of hypotheses and thus avoiding constraint consumption during an application of the *ask* rule:

**Definition 2.20** Let  $(\mathcal{C}, \Vdash_{\mathcal{C}})$  be a constraint system. We define the translation of  $(\mathcal{C}, \Vdash_{\mathcal{C}})$ , which is the linear constraint system  $(\mathcal{C}, \Vdash_{\mathcal{C}})^{\circ}$ , as follows, at the same time as the translation of CC agents to LCC agents:

 $c^{\circ} = !c, \text{ if } c \text{ is an atomic constraint}$   $(c \land d)^{\circ} = c^{\circ} \otimes d^{\circ} \qquad (\exists xc)^{\circ} = \exists xc^{\circ}$   $tell(c)^{\circ} = tell(c^{\circ}) \qquad p(\vec{x})^{\circ} = p(\vec{x})$   $(A \parallel B)^{\circ} = A^{\circ} \parallel B^{\circ} \qquad (A + B)^{\circ} = A^{\circ} + B^{\circ}$   $(\forall \vec{x}(c \to A))^{\circ} = \forall \vec{x}(c^{\circ} \to A^{\circ}) \qquad (\exists xA)^{\circ} = \exists xA^{\circ}$ 

The entailment relation  $\Vdash_{\mathcal{C}}^{\circ}$  is defined by:  $c \Vdash_{\mathcal{C}} d$  iff  $c^{\circ} \Vdash_{\mathcal{C}}^{\circ} d^{\circ}$ .

The relation  $\vdash_{\mathcal{C}}^{\circ}$  is obtained from  $\Vdash_{\mathcal{C}}^{\circ}$  by the rules of linear logic for 1, !,  $\otimes$  and  $\exists$ .

The translation of a CC configuration  $(\vec{x}; c; \Gamma)$  is the LCC configuration  $(\vec{x}; c^{\circ}; \Gamma^{\circ})$ .

<sup>&</sup>lt;sup>2</sup>As an alternative, we could have defined the operational semantics of LCC programs with arbitrary initial stores, all the results of the following section generalize straightforwardly to this case.

For constraints, the above translation is a well-known translation of intuitionistic logic into linear logic [10, p.81], hence:

**Proposition 2.21** Let c and d be constraints:  $c \vdash_{\mathcal{C}} d$  iff  $c^{\circ} \vdash_{\mathcal{C}} c^{\circ} d^{\circ}$ .

We now check that the translations of configurations have the expected behavior:

 $\begin{array}{l} \textbf{Proposition 2.22} \quad Let \ (\vec{x};c;\Gamma) \ and \ (\vec{y};d;\Delta) \ be \ CC \ configurations: \\ (i) \ (\vec{x};c;\Gamma) \equiv (\vec{y};d;\Delta) \ iff \ (\vec{x};c^{\circ};\Gamma^{\circ}) \equiv^{\circ} \ (\vec{y};d^{\circ};\Delta^{\circ}); \\ (ii) \ if \ (\vec{x};c;\Gamma) \longrightarrow_{CC} \ (\vec{y};d;\Delta) \ then \ (\vec{x};c^{\circ};\Gamma^{\circ}) \longrightarrow_{LCC} \ (\vec{y};d^{\circ};\Delta^{\circ}); \\ (iii) \ if \ (\vec{x};c^{\circ};\Gamma^{\circ}) \ \longrightarrow_{LCC} \ (\vec{y};d^{\circ};\Delta^{\circ}) \ then \ (\vec{x};c;\Gamma) \ \longrightarrow_{CC} \ (\vec{y};e;\Delta), \ with \\ e \vdash d. \end{array}$ 

#### **Proof.** (i) is evident.

For (ii), we proceed by induction on  $\longrightarrow_{CC}$ , the only interesting case is the *ask* rule: we suppose

$$(\vec{x}; c; \forall \vec{y}(d \to A), \Gamma) \longrightarrow_{CC} (\vec{x}; c; A[\vec{t}/\vec{y}], \Gamma),$$

using the  $c \vdash_{\mathcal{C}} d[\vec{t}/\vec{y}]$  relation. We thus have  $c \vdash_{\mathcal{C}} c \wedge d[\vec{t}/\vec{y}]$ , and from proposition 2.21,  $c^{\circ} \vdash_{\mathcal{C}} c^{\circ} (c \wedge d[\vec{t}/\vec{y}])^{\circ} = c^{\circ} \otimes d[\vec{t}/\vec{y}]^{\circ}$ . As a consequence

$$(\vec{x};c^{\circ};\forall\vec{y}(d^{\circ}\to A^{\circ}),\Gamma^{\circ})\longrightarrow_{LCC}(\vec{x};c^{\circ};A^{\circ}[\vec{t}/\vec{y}],\Gamma^{\circ}),$$

qed.

For (iii), we proceed by induction on  $\longrightarrow_{LCC}$ . The only interesting case is again the *ask* rule: we suppose

$$(\vec{x}; c^{\circ}; \forall \vec{y} (d^{\circ} \to A^{\circ}), \Gamma^{\circ}) \longrightarrow_{LCC} (\vec{x}; e^{\circ}; A^{\circ}[\vec{t}/\vec{y}], \Gamma^{\circ}),$$

using the relation  $c^{\circ} \vdash_{\mathcal{C}} c^{\circ} d^{\circ}[\vec{t}/\vec{y}] \otimes e^{\circ} = (d \wedge e)^{\circ}$ . Thus from the proposition 2.21,  $c \vdash_{\mathcal{C}} d[\vec{t}/\vec{y}] \wedge e \vdash_{\mathcal{C}} d[\vec{t}/\vec{y}]$ , hence

$$(\vec{x};c;\forall \vec{y}(d \to A), \Gamma) \longrightarrow_{CC} (\vec{x};c;A[\vec{t}/\vec{y}], \Gamma),$$

and  $c \vdash_{\mathcal{C}} e$ , qed.

The above translation is correct w.r.t. the observation of the store and of successes of a CC configuration (case (i) and (ii) of the proposition 2.22).

#### 2.2.3 Example of LCC program

A classical benchmark of expressiveness for concurrent languages is the dining philosophers:  $\mathbb{N}$  philosophers are sitting around a table and alternate thinking and eating. Each one of them has a fork on his right, and thus also on his left, and needs these two forks to eat (the chop-sticks version may be more realistic).

As suggested in [3], this problem has an extremely simple solution in LCC.

The atomic constraints are: fork(I), eat(I,N) for I,N $\in \mathbb{N}$ , and N=M, N $\neq$ M for N,M $\in \mathbb{N}$ ; the entailment relation is trivial.

```
philosopher(I,N) =
    fork(I) \otimes fork(I+1 mod N) \rightarrow
        (tell(eat(I,N)) ||
        eat(I,N) \rightarrow
        (tell(fork(I) \otimes fork(I+1 mod N)) ||
        philosopher(I,N))).

recphilo(M,P) =
    M \neq P \rightarrow (philosopher(M,P) || tell(fork(M)) ||
        recphilo(M+1,P)) ||
    M = P \rightarrow (philosopher(M,P) || tell(fork(M))).

init(N) = recphilo(1,N).
```

It is worth noting that contrarily to a classical CC program, the imperative data structures are encoded directly with linear constraints, instead of streams [29], and that contrarily to the Linda version of [4] there is no need for introducing "tickets", as the guard in the ask can be the tensor product of both forks.

This program enjoys safety and liveness properties: two adjacent philosophers cannot eat at the same time, and at least one philosopher can eat.

A proof of safety of this program is given in section 4, using the phase semantics of linear logic.

#### 3 Logical semantics

#### 3.1 Characterizing CC stores in intuitionistic logic

Let us fix a constraint system  $(\mathcal{C}, \Vdash_{\mathcal{C}})$  and a set of declarations  $\mathcal{D}$ .

**Definition 3.1** Deterministic CC agents are translated into intuitionistic formulas of the following way:

$$tell(c)^{\dagger} = c$$
  

$$p(\vec{x})^{\dagger} = p(\vec{x}) \qquad (\exists x A)^{\dagger} = \exists x A^{\dagger}$$
  

$$(\forall \vec{x}(c \to A))^{\dagger} = \forall \vec{x}(c \Rightarrow A^{\dagger}) \quad (A \parallel B)^{\dagger} = A^{\dagger} \land B^{\dagger}$$

If  $\Gamma$  is the multiset of agents  $(A_1 \dots A_n)$ , one defines  $\Gamma^{\dagger} = A_1^{\dagger} \wedge \dots \wedge A_n^{\dagger}$ . If  $\Gamma = \emptyset$  then  $\Gamma^{\dagger} = 1$ .

The translation  $(\vec{x}; c; \Gamma)^{\dagger}$ ) of a configuration  $(\vec{x}; c; \Gamma)$  is the formula  $\exists \vec{x} (c \land \Gamma^{\dagger})$ .

 $\mathrm{IL}(\mathcal{C},\mathcal{D})$  denotes the deduction system obtained by adding to IL:

- the non-logical axiom  $c \vdash d$  for every  $c \Vdash_{\mathcal{C}} d$  in  $\Vdash_{\mathcal{C}}$ ,
- the non-logical axiom  $p(\vec{x}) \vdash A^{\dagger}$  for every declaration  $p(\vec{x}) = A$  in  $\mathcal{D}$ .

 $\dashv\vdash$  denotes logical equivalence.

**Theorem 3.2 (Soundness)** Let  $(\vec{x}; c; \Gamma)$  and  $(\vec{y}; d; \Delta)$  be deterministic CC configurations.

 $If(\vec{x};c;\Gamma) \equiv (\vec{y};d;\Delta) \ then \ (\vec{x};c;\Gamma)^{\dagger} \dashv \vdash_{IL(\mathcal{C},\mathcal{D})} (\vec{y};d;\Delta)^{\dagger}.$  $If(\vec{x};c;\Gamma) \longrightarrow_{CC}^{*} (\vec{y};d;\Delta) \ then \ (\vec{x};c;\Gamma)^{\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} (\vec{y};d;\Delta)^{\dagger}.$ 

**Proof.** By induction on  $\equiv$  and  $\rightarrow_{CC}$ .

- For parallel composition and  $\alpha$ -conversion, it is immediate.
- For hiding,  $\exists x(A \land B) \dashv \vdash A \land \exists x B$  and  $\exists x A \dashv \vdash A$  so  $x \notin fv(A)$ .
- For tell, congruence and declarations, it is immediate.
- For ask, just note that  $c \land \forall \vec{x}(d \Rightarrow A) \vdash c \land A[\vec{t}/\vec{y}]$  if  $c \Vdash_{\mathcal{C}} d[\vec{t}/\vec{y}]$ , qed.

The converse is true for the observation of stores. Let  $\kappa = (\vec{x}; c; \Gamma)$  be a deterministic CC configuration, and  $\phi$  be a constraint or a procedure name.  $\kappa \xrightarrow{\gg} \phi$  stands for:

- if φ is a constraint: "there exists a configuration (y; d; Δ), such that d ⊢<sub>C</sub> φ and κ −→<sup>\*</sup><sub>CC</sub> (y; d; Δ)",
- if  $\phi$  is a procedure name: "there exists a configuration  $(\vec{y}; d; \phi, \Delta)$ , such that  $fv(\phi) \cap \vec{y} = \emptyset$  and  $\kappa \longrightarrow_{CC}^{*} (\vec{y}; d; \phi, \Delta)$ ".

**Lemma 3.3** Let  $\kappa$  and  $\lambda$  be two deterministic CC configurations such that  $\kappa^{\dagger} = \lambda^{\dagger}$ , and  $\phi$  a constraint or a procedure name.  $\kappa \xrightarrow{\gg} \phi$  iff  $\lambda \xrightarrow{\gg} \phi$ .

**Proof.** One shows by induction on the formula  $\kappa^{\dagger} = \lambda^{\dagger}$  that  $\kappa \xrightarrow{\gg} \phi$  iff  $\lambda \xrightarrow{\gg} \phi$ .

- If  $\kappa^{\dagger} = \lambda^{\dagger}$  is atomic, it is clear.
- If  $\kappa^{\dagger} = \lambda^{\dagger} = \forall \vec{x}(c \Rightarrow A^{\dagger})$ , with c a constraint and A an agent, then  $\kappa$  and  $\lambda$  are necessarily both equal to  $(\emptyset; 1; \forall \vec{x}(c \to A))$ .
- If  $\kappa^{\dagger} = \lambda^{\dagger} = \exists x A^{\dagger}$ , then the only two possibilities for  $\kappa$  and  $\lambda$  are  $(x, \vec{y}; c; \Gamma)$  and  $(\emptyset; 1; \exists x \exists \vec{y}(tell(c) \parallel \Gamma))$ . One implication is thus obvious and the other one a simple corollary of the monotonicity property 2.17.
- If  $\kappa^{\dagger} = \lambda^{\dagger} = A^{\dagger} \wedge B^{\dagger}$ , then the four possibilities for  $\kappa$  and  $\lambda$  are:  $(\emptyset; 1; \Gamma, \Delta)$ (with  $\Gamma^{\dagger} = A^{\dagger}$  and  $\Delta^{\dagger} = B^{\dagger}$ ),  $(\emptyset; 1; A \parallel B)$ ,  $(\emptyset; c; B)$  (if  $A^{\dagger} = c$ , a constraint, i.e. A = c or A = tell(c)) and  $(\emptyset; c \wedge d; \emptyset)$  (if  $A^{\dagger} = c$  and  $B^{\dagger} = d$ , constraints). The induction is useful only in the first case, and the result is evident.

**Lemma 3.4** Let  $\kappa = (\vec{x}; c; \Gamma)$  be a deterministic CC configuration, and  $\phi$  be a constraint or a procedure name.

If  $\kappa^{\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} \phi$ , then  $\kappa \xrightarrow{\gg} \phi$ .

**Proof.** One proves the result for multisets of agents. One shows that if  $A_1^{\dagger}, \ldots, A_n^{\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} \phi$ , where the  $A_i$  are agents and  $\phi$  is either a constraint or a procedure name, then  $(\emptyset; 1; A_1, \ldots, A_n) \xrightarrow{\gg} \phi$ .

It allows one to conclude: indeed let  $(\vec{x}; c; \Gamma)$  be a deterministic CC configuration, and  $\phi$  be a constraint or a procedure name. Note that  $(\vec{x}; c; \Gamma)^{\dagger} = \exists \vec{x}(tell(c) \parallel \Gamma)^{\dagger}$ . Therefore if  $(\vec{x}; c; \Gamma)^{\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} \phi$ , then  $(\vec{x}; 1; tell(c), \Gamma)) \equiv (\emptyset; 1; \exists \vec{x}(tell(c) \parallel \Gamma)) \xrightarrow{\gg} \phi$ . But  $(\vec{x}; 1; tell(c), \Gamma))^{\dagger} = (\vec{x}; c; \Gamma))^{\dagger}$ . So according to lemma 3.3,  $(\vec{x}; c; \Gamma)) \xrightarrow{\gg} \phi$ , qed.

Let us proceed by induction on a sequent calculus proof  $\pi$  of  $A_1^{\dagger}, \ldots, A_n^{\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} \phi$ , where the  $A_i$ 's are agents and  $\phi$  is either a constraint or a procedure name. We shall consider, without loss of generality, that in  $\pi$  the left introduction of  $\forall$  and of  $\Rightarrow$  are always consecutive (if it is not the case, it is well-known that the rules can be permuted to obtain such a proof, see for instance [9]) we will thus group them as a single rule.

First remark that this induction is meaningful. Indeed, one can assume that cuts bear only on non-logical axioms, so that they are of one of the following forms:

$$\frac{\Gamma \vdash p \quad p \vdash \phi}{\Gamma \vdash \phi} \qquad \frac{\Gamma \vdash e \quad e \vdash f}{\Gamma \vdash f}$$

$$\frac{p \vdash \psi}{\Gamma, p \vdash \phi} \quad \frac{e \vdash f}{\Gamma, e \vdash \phi}$$

So, when traveling up through such a proof, the formula on the right of a non-axiom sequent remains either a sub-formula of a constraint, thus itself a constraint, or a procedure name. One the other hand the formulas to the left remain sub-formulas of translations of agents or constraints or procedure names, so they are agents. (Remark that the induction hypothesis requires the result not only for constraints, but also for procedure names.)

Each logical rule simulates a CC transition rule.

- $\pi$  is an axiom: one uses the reflexivity of  $\longrightarrow_{CC}^{*}$  in the case of a logical axiom, the rule *declarations* for an axiom  $p \vdash q$ ; the case of an axiom  $d \vdash_{C} e$  is trivial.
- $\pi$  ends with a cut: the possible cases are the ones enumerated above. Let us consider for instance :

$$\frac{\Gamma^{\dagger} \vdash p \qquad p \vdash \phi}{\Gamma^{\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} p$ , i.e. there exists a configuration  $(\vec{y}; d; p, \Delta)$  such that  $fv(p) \cap \vec{y} = \emptyset$  and  $(\emptyset; 1; \Gamma) \longrightarrow_{CC}^{*} (\vec{y}; d; p, \Delta)$ . Thus  $(\emptyset; 1; \Gamma) \longrightarrow_{CC}^{*} (\vec{y}; d; \phi, \Delta)$ , with  $fv(\phi) \cap \vec{y} = \emptyset$  as  $fv(\phi) \subset fv(p)$ . If  $\phi^{\dagger} = \phi$  is a name of procedure, it is finished. If  $\phi^{\dagger}$  is a constraint c, then  $\phi = tell(c)$  so  $(\emptyset; 1; \Gamma) \longrightarrow_{CC}^{*} (\vec{y}; d \land c; \Delta)$ , qed.

The other cases are similar.

- $\pi$  ends with a left introduction of 1: note that  $(\emptyset; 1; \Gamma, tell(1)) \longrightarrow_{CC}^{*} (\emptyset; 1; \Gamma)$ . By induction hypothesis,  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} \phi$  thus  $(\emptyset; 1; \Gamma, tell(1) \xrightarrow{\gg} \phi, \text{qed.})$
- $\pi$  ends with a weakening:

$$\frac{\Gamma^{\dagger} \vdash \phi}{\Gamma^{\dagger}, A^{\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} \phi$ , thus  $(\emptyset; 1; A, \Gamma) \xrightarrow{\gg} \phi$  thanks to the monotonicity of  $\longrightarrow_{CC}$  (proposition 2.9).

•  $\pi$  ends with a contraction:

$$\frac{\Gamma^{\dagger}, A^{\dagger}, A^{\dagger} \vdash \phi}{\Gamma^{\dagger}, A^{\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; A, A, \Gamma) \xrightarrow{\gg} \phi$ . In this sequence of transitions, some steps activate some occurrence of A, some others activate a sub-agent of  $\Gamma$ . The important point is that for the deterministic agent A, the next transition in which it can further be active (in other words the next action that it can perform) is determined (no +). One can thus assume that in the above execution, each time one activates a sub-agent of an occurrence of A, the same transition with the other occurrence is performed just the next moment, it is of course possible thanks to proposition 2.7. Now starting from the configuration ( $\emptyset$ ; 1;  $A, \Gamma$ ), one simulates the above execution by applying the same transitions to sub-agents of  $\Gamma$ and "contracting" the pairs of transitions for the sub-agents of A: one applies the rule to one of the two copies, always the same one. One then obtains an execution ( $\emptyset$ ; 1;  $A, \Gamma$ )  $\xrightarrow{\gg} \phi$ .

•  $\pi$  ends with:

$$\frac{\Gamma^{\dagger}, A^{\dagger}, B^{\dagger} \vdash \phi}{\Gamma^{\dagger}, A^{\dagger} \land B^{\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; A, B, \Gamma) \xrightarrow{\gg} \phi$ . If  $A^{\dagger}$  and  $B^{\dagger}$  are constraints, there is a priori an ambiguity on the agent C whose translation is  $A^{\dagger} \wedge B^{\dagger}$ : it can be  $tell(A \wedge B)$  or  $tell(A) \parallel tell(B)$ ). However, as the two configurations have the same translation as  $(\emptyset; 1; A, B, \Gamma)$ , according to lemma 3.3,  $(\emptyset; 1; C, \Gamma) \xrightarrow{\gg} \phi$ .

•  $\pi$  ends with:

$$\frac{\Gamma^{\dagger} \vdash \phi \qquad \Delta^{\dagger} \vdash \psi}{\Gamma^{\dagger}, \Delta^{\dagger} \vdash \phi \land \psi}$$

 $\phi \wedge \psi$  is not atomic, so  $\phi$  and  $\psi$  are constraints. The result is now immediate: starting from the configuration  $(\emptyset; 1; \Gamma, \Delta)$ , one just joins the two executions  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} \phi$  and  $(\emptyset; 1; \Delta) \xrightarrow{\gg} \psi$  end to end.

- $\pi$  ends with a right introduction of  $\exists$  (in case  $\phi$  is a constraint): immediate.
- $\pi$  ends with:

$$\frac{\Gamma^{\dagger}, A^{\dagger} \vdash \phi}{\Gamma^{\dagger}, \exists x A^{\dagger} \vdash \phi} x \not\in fv(\Gamma, \phi)$$

By induction hypothesis,  $(\emptyset; 1; A, \Gamma) \xrightarrow{\gg} \phi$ . As  $x \notin fv(\Gamma)$ ,  $(\emptyset; 1; \exists x A, \Gamma) \equiv (x; 1; A, \Gamma)$ , and moreover  $x \notin fv(\phi)$ , so by lemma 3.3,  $(\emptyset; 1; \exists x A, \Gamma) \xrightarrow{\gg} \phi$ , qed.

•  $\pi$  ends with (thanks to the preliminary remark on the permutability of rules):

$$\frac{\Gamma^{\dagger}, A^{\dagger}[\vec{t}/\vec{x}] \vdash \phi \qquad \Delta^{\dagger} \vdash c[\vec{t}/\vec{x}]}{\Gamma^{\dagger}, \Delta^{\dagger}, c[\vec{t}/\vec{x}] \Rightarrow A^{\dagger}[\vec{t}/\vec{x}] \vdash \phi}{\Gamma^{\dagger}, \Delta^{\dagger}, \forall \vec{x}(c \Rightarrow A^{\dagger}) \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; \Delta) \xrightarrow{\gg} c[\vec{t}/\vec{x}]$ , i.e. there exists a configuration  $(\vec{y}; d; \Sigma)$ , such that  $d \vdash_{\mathcal{C}} c[\vec{t}/\vec{x}]$  and  $(\emptyset; 1; \Delta) \longrightarrow_{CC}^{*} (\vec{y}; d; \Sigma)$ . Thus  $(\emptyset; 1; \forall \vec{x}(c \rightarrow A), \Delta) \longrightarrow_{CC}^{*} (\vec{y}; d; \forall \vec{x}(c \rightarrow A), \Sigma) \longrightarrow_{CC}^{*} (\vec{y}; d; A[\vec{t}/\vec{x}], \Sigma)$ . Therefore,  $(\emptyset; 1; \forall \vec{x}(c \rightarrow A), \Delta, \Gamma) \longrightarrow_{CC}^{*} (\vec{y}; d; A[\vec{t}/\vec{x}], \Sigma, \Gamma)$ . Moreover by induction hypothesis,  $(\emptyset; 1; A[\vec{t}/\vec{x}], \Gamma) \xrightarrow{\gg} \phi$ , whence  $(\emptyset; 1; \forall \vec{x}(c \rightarrow A), \Delta, \Gamma) \longrightarrow_{C}^{*} \phi$ .

Now, for a set S of constraints, let us note  $\downarrow S = \{c \in \mathcal{C} \mid \exists d \in S, d \vdash_{\mathcal{C}} c\},\$ we get:

**Theorem 3.5 (Observation of deterministic stores)** Let A be a deterministic CC agent, define  $\mathcal{L}^{store}(\mathcal{D}.A) = \{c \in \mathcal{C} \mid A^{\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} c\}$  we have:

$$\mathcal{L}^{store}(\mathcal{D}.A) = \downarrow \mathcal{O}_{CC}^{store}(\mathcal{D}.A)$$

**Proof.** One inclusion is obvious by applying the previous theorem, it is just the definition of an accessible store, the other is a direct consequence of theorem 3.2. □

The characterization of stores for non-deterministic configurations is not obvious in the framework of intuitionistic logic: indeed on one hand the simple idea of translating the operator of choice + by disjunction  $\lor$  requires to modify the operational semantics of + (e.g. for soundness, because  $A \lor B \not\vdash A$ ), and on the other hand the idea of translating + by conjunction preserves the soundness, but not the characterization of stores because, for instance, the store  $c \land d$  is not accessible from the configuration  $(\emptyset; 1; tell(c) + tell(d))$ .

However we shall see in the more general framework of linear CC (section 3.3) that a logical characterization of *must* properties, i.e. properties that are true in all possible non-deterministic configurations, is possible in linear logic.

#### 3.2 Characterizing CC and LCC stores and successes in intuitionistic linear logic

The observation of stores is important, however it represents only one aspect of the operational behavior of CC programs.

Consider the following three programs :

$$p(x) = x \ge 1$$

$$p(x) = x \ge 1 \parallel p(x)$$

$$p(x) = x \ge 1 \parallel (false \to A).$$

They define the same stores  $(x \ge 1)$ , thus they are equivalent w.r.t. the observation of stores, whereas the first one terminates on a success, the second one loops and the third one suspends.

As is shown by the following counter-examples, neither the successes nor the suspensions are characterizables in intuitionistic logic:

- ⊢: In general it is false that A ⊢ B (where B is a success or a suspension) implies (Ø;1;A) →<sub>LCC</sub> (Ø;1;B). For instance c → d ⊢ d but c → d can suspend, and thus have no success. Besides d ⊢ d ∧ (c → d) and if d does not imply c, d || (c → d) is a suspension, whereas the constraint c is not a suspension.
- ⊢: One has similar problems with ⊢. d∧(c ⇒ A) ⊢ d whereas d || (c → A) suspend as soon as d ⊢ c. Besides d∧(d ⇒ e) ⊢ d ⇒ e, but d || (d → e) has a success (d∧ e) and does not suspend.
- $\dashv\vdash$ : Similarly, for the equivalence  $\dashv\vdash$ , let us suppose that d does not imply c, and let us consider the following equivalence:  $d \land (c \Rightarrow d) \dashv\vdash d$ . One cannot conclude anything about the operational behavior of the agents tell(d) and  $d \parallel (c \to d)$ .

The obstacle is the structural rule of (left) weakening:

$$\frac{\Gamma \vdash B}{\Gamma, A \vdash B}$$

Girard's linear logic [10] is a refinement of the contraction and weakening rules of usual logic. It seems therefore natural to interpret CC programs in linear logic.

Let us fix a linear constraint system  $(\mathcal{C}, \Vdash_{\mathcal{C}})$  and a set of declarations  $\mathcal{D}$ .

**Definition 3.6** LCC agents are translated into formulas in the following way:

$$\begin{aligned} tell(c)^{\ddagger} &= c & p(\vec{x})^{\ddagger} = p(\vec{x}) \\ \forall \vec{y}(c \rightarrow A)^{\ddagger} &= \forall \vec{y} \ (c \multimap A^{\ddagger}) & (A \parallel B)^{\ddagger} = A^{\ddagger} \otimes B^{\ddagger} \\ (A + B)^{\ddagger} &= A^{\ddagger} \& B^{\ddagger} & (\exists x A)^{\ddagger} = \exists x A^{\ddagger} \end{aligned}$$

If  $\Gamma$  is the multiset of agents  $(A_1 \dots A_n)$ , define  $\Gamma^{\ddagger} = A_1^{\ddagger} \otimes \dots \otimes A_n^{\ddagger}$ . If  $\Gamma = \emptyset$  then  $\Gamma^{\ddagger} = 1$ .

The translation  $(c, \Gamma)^{\ddagger}$  of a configuration  $(\vec{x}; c; \Gamma)$  is the formula  $\exists \vec{x} (c \otimes \Gamma^{\ddagger})$ .

 $ILL(\mathcal{C},\mathcal{D})$  denotes the deduction system obtained by adding to ILL:

- the non-logical axiom  $c \vdash d$  for every  $c \Vdash_{\mathcal{C}} d$  in  $\Vdash_{\mathcal{C}}$ ,
- the non-logical axiom  $p(\vec{x}) \vdash A^{\ddagger}$  for every declaration  $p(\vec{x}) = A$  in  $\mathcal{D}$ .

**Theorem 3.7 (Soundness)** Let  $(\vec{x}; c; \Gamma)$  and  $(\vec{y}; d; \Delta)$  be LCC configurations. If  $(\vec{x}; c; \Gamma) \equiv (\vec{y}; d; \Delta)$  then  $(\vec{x}; c; \Gamma)^{\ddagger} \dashv \vdash_{ILL(\mathcal{C}, \mathcal{D})} (\vec{y}; d; \Delta)^{\ddagger}$ . If  $(\vec{x}; c; \Gamma) \longrightarrow_{LCC}^{*} (\vec{y}; d; \Delta)$  then  $(\vec{x}; c; \Gamma)^{\ddagger} \vdash_{ILL(\mathcal{C}, \mathcal{D})} (\vec{y}; d; \Delta)^{\ddagger}$ .

**Proof.** The proof is essentially the same as in intuitionistic logic. Note that for the operator of choice + translated by the additive conjunction &,  $A \& B \vdash A$  and  $A \& B \vdash B$ .

Conversely, one can characterize the observation of successes, even in presence of the operator of explicit choice +:

#### Notation:

Let  $\kappa = (\vec{x}; c; \Gamma)$  be an LCC configuration, and  $\phi$  be a constraint or a procedure name.  $\kappa \xrightarrow{\gg} \phi$  stands for:

- if φ is a constraint: "there exists a configuration (ÿ; d; Ø), such that d ⊢<sub>C</sub> φ and κ −→<sup>\*</sup><sub>LCC</sub> (ÿ; d; Ø)",
- if  $\phi$  is a procedure name: "there exists a configuration  $(\vec{y}; d; \phi)$ , such that  $fv(\phi) \cap \vec{y} = \emptyset, d \vdash_{\mathcal{C}} 1$  and  $\kappa \longrightarrow_{LCC}^{*} (\vec{y}; d; \phi)$ ".

**Lemma 3.8** Let  $\kappa$  and  $\lambda$  be two configurations LCC such that  $\kappa^{\ddagger} = \lambda^{\ddagger}$ , and  $\phi$  be a constraint or a procedure name.

 $\kappa \xrightarrow{\gg} \phi \text{ iff } \lambda \xrightarrow{\gg} \phi.$ 

**Proof.** Again the proof is essentially the same as in intuitionistic logic, the difference between  $\kappa$  and  $\lambda$  amounts to non performed *tell*'s, or to  $tell(c \otimes d)$  vs  $tell(c) \parallel tell(d)$ .

**Lemma 3.9** Let  $(\emptyset; 1; \Gamma)$  be an LCC configuration such that  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} \phi$  and x be a variable such that  $x \notin fv(\phi)$ . Then  $(x; 1; \Gamma) \xrightarrow{\gg} \phi$ 

**Proof.** Let  $\Delta$  be the agents obtained by replacing all bounded occurrences of x in  $\Gamma$  by a fresh variable z. We have  $(\emptyset; 1; \Gamma) \equiv (\emptyset; 1; \Delta)$  thus  $(\emptyset; 1; \Delta) \xrightarrow{\gg} \phi$ .

If  $\phi$  is a constraint then  $(\emptyset; 1; \Delta) \longrightarrow^* (\vec{y}; d; \emptyset)$  with  $\exists \vec{y}d \vdash_{\mathcal{C}} \phi$ . One can then show by an easy induction on this derivation that  $(x; 1; \Delta) \longrightarrow^* (x, \vec{y}; d; \emptyset)$  (the only non-trivial case is the use of the Hiding rule, but as x has no bounded occurrence in  $\Delta$ , the same rule can be used in the derivation for  $(x, \vec{y}; d; \emptyset)$ ). As  $x \notin fv(\phi)$  we get  $\exists x, \vec{y} \ d \vdash_{\mathcal{C}} \phi$  so  $(x; 1; \Delta) \xrightarrow{\gg} \phi$ . If  $\phi$  is a procedure name we also get  $(x; 1; \Delta) \xrightarrow{\gg} \phi$  in the same manner. The result then follows from the observation that  $(x; 1; \Delta) \equiv (x; 1; \Gamma)$ .

**Lemma 3.10** Let  $\kappa = (\vec{x}; c; \Gamma)$  be an LCC configuration, and  $\phi$  be a constraint or a procedure name.

If  $\kappa^{\dagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} \phi$ , then  $\kappa \xrightarrow{\gg} \phi$ .

**Proof.** One proves the result for multisets of agents: if  $A_1^{\dagger}, \ldots, A_n^{\dagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} \phi$ , then  $(\emptyset; 1; A_1, \ldots, A_n) \xrightarrow{\gg} \phi$ .

It allows one to conclude: indeed let  $(\vec{x}; c; \Gamma)$  be a configuration, and  $\phi$  be a constraint or a procedure name. Note that  $(\vec{x}; c; \Gamma)^{\dagger} = \exists \vec{x}(tell(c) \parallel \Gamma)^{\dagger}$ . Therefore if  $(\vec{x}; c; \Gamma)^{\dagger} \vdash_{ILL(\mathcal{C}, \mathcal{D})} \phi$ , then  $(\vec{x}; 1; tell(c), \Gamma)) \equiv (\emptyset; 1; \exists \vec{x}(tell(c) \parallel \Gamma)) \xrightarrow{\Longrightarrow} \phi$ . But  $(\vec{x}; 1; tell(c), \Gamma))^{\dagger} = (\vec{x}; c; \Gamma)^{\dagger}$ . So according to lemma 3.3,  $(\vec{x}; c; \Gamma) \xrightarrow{\Longrightarrow} \phi$ , qed.

One proceeds by induction on a sequent calculus proof  $\pi$  of  $A_1^{\dagger}, \ldots, A_n^{\dagger} \vdash \phi$ . We shall consider, without loss of generality, that in  $\pi$  the left introduction of  $\forall$  and of  $\multimap$  are always consecutive (if it is not the case, the rules can be permuted to obtain such a proof, see for instance [20], noting that !, that is the only case of impermutability with  $\forall$ , appears only in the constraint part and thus not below a  $\multimap$ ), we will thus group them as a single rule.

Each logical rule simulates an LCC transition rule (we will group left introductions of  $\forall$  and of  $\neg as$  in lemma 3.4).

- $\pi$  is an axiom: one uses the reflexivity of  $\longrightarrow^*$  in the case of a logical axiom, the rule *declarations* for an axiom  $p \vdash q$ ; the case of an axiom  $d \vdash_{\mathcal{C}} e$  is trivial.
- $\pi$  ends with a cut. Let us consider for instance :

$$\frac{\Gamma^{\dagger} \vdash p \quad \overline{p \vdash \phi}}{\Gamma^{\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} p$ , i.e. there exists a configuration  $(\vec{y}; d; p)$  such that  $fv(p) \cap \vec{y} = \emptyset$ ,  $\exists \vec{y}d \vdash_{\mathcal{C}} 1$  and  $(\emptyset; 1; \Gamma) \longrightarrow^* (\vec{y}; d; p)$ . Thus  $(\emptyset; 1; \Gamma) \longrightarrow^* (\vec{y}; d; \phi); fv(\phi) \cap \vec{y} = \emptyset$  as  $fv(\phi) \subset fv(p)$ . If  $\phi^{\dagger} = \phi$  is a procedure name, it is finished. If  $\phi^{\dagger}$  is a constraint c, then  $\phi = tell(c)$  whence  $(\emptyset; 1; \Gamma) \longrightarrow^* (\vec{y}; d \otimes c; \emptyset)$  and  $d \otimes c \vdash_{\mathcal{C}} c$ , qed.

The other cases are similar.

- $\pi$  ends with a left introduction of 1: note that  $(\emptyset; 1; \Gamma, tell(1)) \longrightarrow^* (\emptyset; 1; \Gamma)$ . By induction hypothesis,  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} \phi$  thus  $(\emptyset; 1; \Gamma, tell(1) \xrightarrow{\gg} \phi, \text{qed.})$
- $\pi$  ends with:

$$\frac{\Gamma^{\dagger}, A^{\dagger}, B^{\dagger} \vdash \phi}{\Gamma^{\dagger}, A^{\dagger} \otimes B^{\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; A, B, \Gamma) \xrightarrow{\gg} \phi$ . If  $A^{\dagger}$  and  $B^{\dagger}$  are constraints, there is a priori an ambiguity on the agent C whose translation is  $A^{\dagger} \otimes B^{\dagger}$ : it can be  $tell(A \otimes B)$  or  $tell(A) \parallel tell(B)$ ). However, as the two configurations have the same translation as  $(\emptyset; 1; A, B, \Gamma)$ , according to lemma 3.3,  $(\emptyset; 1; C, \Gamma) \xrightarrow{\gg} \phi$ .

•  $\pi$  ends with:

$$\frac{\Gamma^{\dagger} \vdash \phi \quad \Delta^{\dagger} \vdash \psi}{\Gamma^{\dagger}, \Delta^{\dagger} \vdash \phi \otimes \psi}$$

 $\phi \otimes \psi$  is not atomic, so  $\phi$  and  $\psi$  are constraints. The result is now immediate: starting from the configuration  $(\emptyset; 1; \Gamma, \Delta)$ , one just joins the two executions  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} \phi$  and  $(\emptyset; 1; \Delta) \xrightarrow{\gg} \psi$  end to end.

•  $\pi$  ends with:

$$\frac{\Gamma^{\dagger}, A^{\dagger} \vdash \phi}{\Gamma^{\dagger}, A^{\dagger} \& B^{\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; A, \Gamma) \xrightarrow{\gg} \phi$ , Now  $(\emptyset; 1; A + B, \Gamma) \longrightarrow^* (\emptyset; 1; A, \Gamma)$ , therefore  $(\emptyset; 1; A + B, \Gamma) \xrightarrow{\gg} \phi$ .

- $\pi$  ends with a right introduction of  $\exists$  (in case  $\phi$  is a constraint): immediate.
- $\pi$  ends with:

$$\frac{\Gamma^{\dagger}, A^{\dagger} \vdash \phi}{\Gamma^{\dagger}, \exists x A^{\dagger} \vdash \phi} \ x \not\in fv(\Gamma, \phi)$$

By induction hypothesis,  $(\emptyset; 1; A, \Gamma) \xrightarrow{\gg} \phi$ . As  $x \notin fv(\Gamma)$ ,  $(\emptyset; 1; \exists xA, \Gamma) \equiv (x; 1; A, \Gamma)$ , and moreover  $x \notin fv(\phi)$ , so by lemma 3.9,  $(\emptyset; 1; \exists xA, \Gamma) \xrightarrow{\gg} \phi$ , qed.

•  $\pi$  ends with (thanks to the preliminary remark on the permutability of rules):

$$\frac{\Gamma^{\dagger}, A^{\dagger}[\vec{t}/\vec{x}] \vdash \phi \quad \Delta^{\dagger} \vdash c[\vec{t}/\vec{x}]}{\Gamma^{\dagger}, \Delta^{\dagger}, (c[\vec{t}/\vec{x}] \multimap A^{\dagger}[\vec{t}/\vec{x}]) \vdash \phi} \frac{\Gamma^{\dagger}, \Delta^{\dagger}, (c[\vec{t}/\vec{x}] \multimap A^{\dagger}[\vec{t}/\vec{x}]) \vdash \phi}{\Gamma^{\dagger}, \Delta^{\dagger}, \forall \vec{x} (c \multimap A^{\dagger}) \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; \Delta) \xrightarrow{\gg} c[\vec{t}/\vec{x}]$ , i.e. there exists a configuration  $(\vec{y}; d; \emptyset)$ , such that  $\exists \vec{y} d \vdash_{\mathcal{C}} c[\vec{t}/\vec{x}]$  and  $(\emptyset; 1; \Delta) \longrightarrow^* (\vec{y}; d; \emptyset)$ . Thus by applying the *ask* rule, one obtains  $(\emptyset; 1; \forall \vec{x} (c \to A), \Delta) \longrightarrow^* (\vec{y}; d; \forall \vec{x} (c \to A)) \longrightarrow^* (\vec{y}; 1; A[\vec{t}/\vec{x}])$ . Therefore,  $(\emptyset; 1; \forall \vec{x} (c \to A), \Delta, \Gamma) \longrightarrow^* (\vec{y}; 1; A[\vec{t}/\vec{x}], \Gamma)$ . Moreover by induction hypothesis,  $(\emptyset; 1; A[\vec{t}/\vec{x}], \Gamma) \xrightarrow{\gg} \phi$ , whence  $(\emptyset; 1; \forall \vec{x} (c \to A), \Delta, \Gamma) \xrightarrow{\gg} \phi$ .

•  $\pi$  ends with a dereliction:

$$\frac{\Gamma^{\dagger}, c \vdash \phi}{\Gamma^{\dagger}, !c \vdash \phi}$$

It is clear, just recall that  $!c \vdash c$ .

- $\pi$  ends with a promotion: in that case all the formulas are necessarily constraints, therefore it is immediate.
- $\pi$  ends with a weakening:

$$\frac{\Gamma^{\dagger} \vdash \phi}{\Gamma^{\dagger}, !c \vdash \phi}$$

with c a constraint. By induction hypothesis,  $(\emptyset; 1; \Gamma) \xrightarrow{\gg} \phi$ , so  $(\emptyset; 1; tell(!c), \Gamma) \xrightarrow{\gg} \phi$  (one performs the *tell*, noting that  $!c \vdash_{\mathcal{C}} 1$ ).

•  $\pi$  ends with a contraction:

$$\frac{\Gamma^{\dagger}, !c, !c \vdash \phi}{\Gamma^{\dagger}, !c \vdash \phi}$$

with c a constraint. By induction hypothesis,  $(\emptyset; 1; tell(!c), tell(!c), \Gamma) \xrightarrow{\gg} \phi$ . Obviously having two occurrences of the agent tell(!c) changes nothing because  $!c \otimes !c \dashv \vdash !c$ . Therefore  $(\emptyset; 1; tell(!c), \Gamma) \xrightarrow{\gg} \phi$  holds as well.

**Theorem 3.11 (Observation of successes)** Let A be an agent LCC and c be a linear constraint. Define  $\mathcal{LL}^{success}(\mathcal{D}.A) = \{c \in \mathcal{C} | A^{\ddagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} c\}$ . We have

$$\mathcal{LL}^{success}(\mathcal{D}.A) = \downarrow \mathcal{O}_{LCC}^{success}(\mathcal{D}.A).$$

**Proof.** Evident by applying the previous lemma to the configuration  $(\emptyset; 1; A)$ .

Recall that  $\top$  is the additive true constant, which is neutral for & (see the appendix). Let, for a set S of linear constraints,  $\Downarrow S = \{c \in \mathcal{C} \mid \exists d \in S, d > c\}$ .

**Theorem 3.12 (Observation of stores)** Let A be an LCC agent and c be a linear constraint. Define  $\mathcal{LL}^{store}(\mathcal{D}.A) = \{c \in \mathcal{C} | A^{\ddagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} c \otimes \top\}$ . We have

$$\mathcal{LL}^{store}(\mathcal{D}.A) = \Downarrow \mathcal{O}_{LCC}^{store}(\mathcal{D}.A).$$

**Proof.** Simply use theorem 3.11, above the right introduction of the tensor connective in  $c \otimes \top$  and note that the property is preserved by left introduction rules.

Thanks to the translation of CC into LCC (section 2.2, proposition 2.22), this characterization of stores and successes in linear logic holds also for CC.

#### 3.3 Must properties

So far we have been concerned with "May" properties of LCC programs, i.e. properties that stand for some branch of the derivation tree. "Must" properties, i.e. properties that are true on all branches of the derivation tree, are also to be considered, for instance when looking at liveness properties. We show that must stores and must successes can be characterized logically using disjunction. The operational semantics has to be adapted to multisets of configurations, called frontiers, which keep track of all the alternatives.

#### 3.3.1 Frontier calculus

A frontier  $\Phi$  is a multiset of configurations, noted  $\langle \kappa_1, \dots, \kappa_n \rangle$  where each  $\kappa_i$ is a configuration  $(\vec{x}_i; c_i; \Gamma_i)$ . The structural congruence  $\equiv$  on configurations is kept unchanged. The transition relation  $\longrightarrow_{LCC}$  is extended to a transition relation  $\Longrightarrow_{LCC}$  on frontiers in the obvious way, the only difference being for the non-deterministic choice:

#### Definition 3.13 (Frontier operational semantics)

$\mathcal{O}^{store}_{CC''}(\mathcal{D}.A) = \{ c \in \mathcal{C} \mid$	$(\emptyset; 1; A) \Longrightarrow_{LCC}^{*} \langle (\vec{x}_1; d_1; \Gamma_1), \cdots, (\vec{x}_n; d_n; \Gamma_n) \rangle,$
	$\exists \vec{x_1} d_1 \vdash_{\mathcal{C}} c, \dots, \exists \vec{x_n} d_n \vdash_{\mathcal{C}} c \}$
$\mathcal{O}^{store}_{LCC''}(\mathcal{D}.A) = \{ c \in \mathcal{C} \mid$	$(\emptyset; 1; A) \Longrightarrow_{LCC}^{*} \langle (\vec{x}_1; d_1; \Gamma_1), \cdots, (\vec{x}_n; d_n; \Gamma_n) \rangle,$
	$\exists \vec{x_1} d_1 \rangle c, \dots, \exists \vec{x_n} d_n \rangle c \}$
$\mathcal{O}_{LCC''}^{success}(\mathcal{D}.A) = \{ c \in \mathcal{C} \mid $	$(\emptyset; 1; A) \Longrightarrow_{LCC}^{*} \langle (\vec{x}_1; d_1; \emptyset), \cdots, (\vec{x}_n; d_n; \emptyset) \rangle,$
	$\exists \vec{x_1} d_1 \vdash_{\mathcal{C}} c, \dots, \exists \vec{x_n} d_n \vdash_{\mathcal{C}} c \}$

The frontier transition relation  $\Longrightarrow_{CC}$  and the operational semantics  $\mathcal{O}_{CC''}^{store}$ and  $\mathcal{O}_{CC''}^{success}$  for CC are defined similarly with *Tell* and *Ask* rules instead of the *LinearTell* and *LinearAsk* rules.

LinearTell	$\langle (\vec{x}; c; tell(d), \Gamma), \Phi \rangle \Longrightarrow_{LCC} \langle (\vec{x}; c \otimes d; \Gamma), \Phi \rangle$
LinearAsk	$\frac{c \vdash_{\mathcal{C}} d \otimes e[\vec{t}/\vec{y}]}{\langle (\vec{x}; c; \forall \vec{y}(e \to A), \Gamma), \Phi \rangle \Longrightarrow_{LCC} \langle (\vec{x}; d; A[\vec{t}/\vec{y}], \Gamma), \Phi \rangle}$
Procedure calls	$\frac{(p(\vec{y}) = A) \in P}{\langle (\vec{x}; c; p(\vec{y}), \Gamma), \Phi \rangle \Longrightarrow_{LCC} \langle (\vec{x}; c; A, \Gamma), \Phi \rangle}$
=	$\frac{(\vec{x};c;\Gamma) \equiv (\vec{x}';c';\Gamma') \Longrightarrow_{LCC} (\vec{y}';d';\Delta') \equiv (\vec{y};d;\Delta)}{\langle (\vec{x};c;\Gamma),\Phi \rangle \Longrightarrow_{LCC} \langle (\vec{y};d;\Delta),\Phi \rangle}$
Blind choice	$\langle (\vec{x}; c; A + B, \Gamma), \Phi \rangle \Longrightarrow_{LCC} \langle (\vec{x}; c; A, \Gamma), (\vec{x}; c; B, \Gamma), \Phi \rangle$

Table 3: LCC frontier transition relation

#### 3.3.2 Logical semantics.

The translation † (resp. ‡) of CC (resp. LCC) configurations into intuitionistic (resp. linear) formulas is changed for disjunctive agents and extended to frontiers by:

$$\begin{aligned} \langle \kappa_1, \cdots, \kappa_n \rangle^{\dagger\dagger} &= (\kappa_1)^{\dagger\dagger} \vee \cdots \vee (\kappa_n)^{\dagger\dagger} \\ (A+B)^{\dagger\dagger} &= A^{\dagger\dagger} \vee B^{\dagger\dagger} & tell(c)^{\dagger\dagger} &= c \\ p(\vec{x})^{\dagger\dagger} &= p(\vec{x}) & (\exists xA)^{\dagger\dagger} &\equiv \exists xA^{\dagger\dagger} \\ (\forall \vec{x}(c \to A))^{\dagger\dagger} &= \forall \vec{x}(c \Rightarrow A^{\dagger\dagger}) & (A \parallel B)^{\dagger\dagger} &= A^{\dagger\dagger} \wedge B^{\dagger\dagger} \end{aligned}$$

$$\begin{aligned} \langle \kappa_1, \cdots, \kappa_n \rangle^{\ddagger\dagger} &= (\kappa_1)^{\ddagger\dagger} \oplus \cdots \oplus (\kappa_n)^{\ddagger\dagger} & (A+B)^{\ddagger\dagger} &= A^{\ddagger\dagger} \oplus B^{\ddagger\dagger}, \\ tell(c)^{\ddagger\dagger} &= c & p(\vec{x})^{\ddagger\dagger} &= p(\vec{x}) \\ \forall \vec{y}(c \to A)^{\ddagger\dagger} &= \forall \vec{y} (c \multimap A^{\ddagger\dagger}) & (A \parallel B)^{\ddagger\dagger} &= A^{\ddagger\ddagger} \otimes B^{\ddagger\ddagger}, \\ (A+B)^{\ddagger\dagger} &= A^{\ddagger\ddagger} \& B^{\ddagger\ddagger} & (\exists xA)^{\ddagger\ddagger} &\equiv \exists xA^{\ddagger\ddagger} \end{aligned}$$

The soundness of the translation is proved by a simple induction:

**Theorem 3.14 (Soundness of frontier transitions)** Let  $\Phi$  and  $\Psi$  be two frontiers. If  $\Phi \Longrightarrow_{CC} \Psi$  then  $\Phi^{\dagger\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} \Psi^{\dagger\dagger}$ . If  $\Phi \Longrightarrow_{LCC} \Psi$  then  $\Phi^{\dagger\ddagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} \Psi^{\ddagger\ddagger}$ .

**Theorem 3.15 (Observation of frontier stores in IL)** Let A be an LCC agent, define  $\mathcal{L}^{store}(\mathcal{D}.A) = \{c \in \mathcal{C} \mid A^{\dagger \dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} c\}$  we have:

$$\mathcal{L}^{store}(\mathcal{D}.A) = \downarrow \mathcal{O}^{store}_{CC''}(\mathcal{D}.A)$$

**Proof.** One inclusion is shown by induction on a proof of  $A^{\dagger} \vdash_{IL(\mathcal{C},\mathcal{D})} c$  as in lemma 3.4. Compared to lemma 3.4, there is just an additional induction step:

$$\frac{\Gamma^{\dagger\dagger}, A^{\dagger\dagger} \vdash \phi}{\Gamma^{\dagger\dagger}, A^{\dagger\dagger} \lor B^{\dagger\dagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; A, \Gamma) \xrightarrow{\gg} \phi$  and  $(\emptyset; 1; B, \Gamma) \xrightarrow{\gg} \phi$ . Now  $(\emptyset; 1; A + B, \Gamma) \Longrightarrow^* \langle (\emptyset; 1; A, \Gamma), (\emptyset; 1; B, \Gamma) \rangle$ , and therefore  $(\emptyset; 1; A + B, \Gamma) \xrightarrow{\gg} \phi$ , ged.

As usual, the other inclusion is a direct consequence of the soundness theorem.  $\hfill \Box$ 

**Theorem 3.16 (Observation of frontier stores and successes in ILL)** Let A be an LCC agent define  $\mathcal{LL}^{''store}(\mathcal{D}.A) = \{c \in \mathcal{C} \mid A^{\ddagger \ddagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} c \otimes \top\}$ and  $\mathcal{LL}^{''success}(\mathcal{D}.A) = \{c \in \mathcal{C} \mid A^{\ddagger \ddagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} c\}$  we have:

 $\mathcal{LL}''^{store}(\mathcal{D}.A) = \Downarrow \mathcal{O}^{store}_{LCC''}(\mathcal{D}.A) \qquad \mathcal{LL}''^{success}(\mathcal{D}.A) = \downarrow \mathcal{O}^{success}_{LCC''}(\mathcal{D}.A)$ 

**Proof.** For the first inclusion, we first prove the result for successes, for stores we apply the same argument as in the proof of theorem 3.12. Proceed by induction on a proof of  $A^{\ddagger\ddagger} \vdash_{ILL(\mathcal{C},\mathcal{D})} c$  as in lemma 3.10. The only difference with the proof of lemma 3.10 is the following induction step:

$$\frac{\Gamma^{\ddagger\ddagger}, A^{\ddagger\ddagger} \vdash \phi \qquad \Gamma^{\ddagger\ddagger}, B^{\ddagger\ddagger} \vdash \phi}{\Gamma^{\ddagger\ddagger}, A^{\ddagger\ddagger} \oplus B^{\ddagger\ddagger} \vdash \phi}$$

By induction hypothesis,  $(\emptyset; 1; A, \Gamma) \xrightarrow{\cong} \phi$  and  $(\emptyset; 1; B, \Gamma) \xrightarrow{\cong} \phi$ . Now  $(\emptyset; 1; A+B, \Gamma) \Longrightarrow^* (\emptyset; 1; A, \Gamma) + (\emptyset; 1; B, \Gamma)$ , and therefore  $(\emptyset; 1; A+B, \Gamma) \xrightarrow{\cong} \phi$ , qed. The second inclusion is obtained via soundness.

#### 4 Phase semantics

#### 4.1 Phase semantics of intuitionistic linear logic

Phase semantics is the natural provability semantics of linear logic [10]. It will also reveal useful for proving safety properties of CC programs, through the links between linear logic and CC. We only need here a fragment of intuitionistic linear logic ( $\otimes$ , & and  $\neg$ , which correspond respectively to the parallel, choice and blocking ask operators, as shown in section 3.2). Nevertheless it is simpler to recall Okada's definition of the phase semantics for full intuitionistic LL [24] and to extend it to constants (1, 0,  $\top$ ).

The definition of formulas and the sequent calculus are recalled in appendix A.

**Definition 4.1** A phase space  $\mathbf{P} = (P, \cdot, 1, \mathcal{F})$  is a commutative monoid  $(P, \cdot, 1)$  together with a set  $\mathcal{F}$  of subsets of P, whose elements are called facts, such that:

 $-\mathcal{F}$  is closed under arbitrary intersection,

- for all  $A \subset P$ , for all  $F \in \mathcal{F}$ ,  $A \multimap F = \{x \in P : \forall a \in A, a \cdot x \in F\}$  is a fact.

As we shall see, facts correspond to ILL formulas and thus to LCC agents (cf. section 3.2).

Note that facts are closed under linear implication  $\multimap$ . Here are a few noticeable facts: the greatest fact  $\top = P$ , the smallest fact  $\mathbf{0}$ , and  $\mathbf{1} = \bigcap \{F \in \mathcal{F} : 1 \in F\}$ .

A parametric fact A is a total function from V to  $\mathcal{F}$  assigning to each variable x a fact A(x). Any fact can be seen as a constant parametric fact, and any operation defined on facts can be extended to parametric facts:  $(A \star B)(x) = A(x) \star B(x)$ .

Let A, B be (parametric) facts, define the following facts:

$$\begin{array}{rcl} A \& B &=& A \cap B, \\ A \otimes B &=& \bigcap \{F \in \mathcal{F} : A \cdot B \subset F\}, \\ A \oplus B &=& \bigcap \{F \in \mathcal{F} : A \cup B \subset F\}, \\ \exists x A &=& \bigcap \{F \in \mathcal{F} : (\bigcup_{x \in V} A(x)) \subset F\}, \\ \forall x A &=& \bigcap \{F \in \mathcal{F} : (\bigcap_{x \in V} A(x)) \subset F\}. \end{array}$$

**Definition 4.2** An enriched phase space is a phase space  $(P, \cdot, 1, \mathcal{F})$  together with a subset O of  $\mathcal{F}$ , whose elements are called open facts, such that:

- -O is closed under arbitrary  $\oplus$  (in particular there is a greatest open fact),
- -1 is the greatest open fact,
- -O is closed under finite  $\otimes$ ,
- $-\otimes$  is idempotent on O (if  $A \in O$  then  $A \otimes A = A$ ).

!A is defined as the greatest open fact contained in A.

The set of facts has been provided with operators corresponding to ILL connectives (and therefore to LCC operators), we now translate formulas into facts.

**Definition 4.3** Given an enriched phase space, a valuation is a mapping  $\eta$  from atomic formulas to facts such that  $\eta(\top) = \top$ ,  $\eta(\mathbf{1}) = \mathbf{1}$  and  $\eta(\mathbf{0}) = \mathbf{0}$ .

The interpretation  $\eta(A)$  (resp.  $\eta(\Gamma)$ ) of a formula A (resp. of a context  $\Gamma$ ) is defined inductively in the obvious way:

$$\begin{split} \eta(A \otimes B) &= \eta(A) \otimes \eta(B), \\ \eta(A \multimap B) &= \eta(A) \multimap \eta(B), \\ \eta(A \otimes B) &= \eta(A) \multimap \eta(B), \\ \eta(A \otimes B) &= \eta(A) \otimes \eta(B), \\ \eta(A \oplus B) &= \eta(A) \oplus \eta(B), \\ \eta((\Gamma, \Delta)) &= \eta(\Gamma) \otimes \eta(\Delta), \\ \eta(\forall xA) &= \forall x \eta(A), \\ \eta(\exists xA) &= \exists x \eta(A), \\ \eta(\Gamma) &= \mathbf{1} \text{ if } \Gamma \text{ is empty.} \end{split}$$

Sequents are interpreted as follows:  $\eta(\Gamma \vdash A) = \eta(\Gamma) \multimap \eta(A)$ . This brings one to defining a notion of validity:

#### **Definition 4.4 (Validity)** Define:

**P**,  $\eta \models (\Gamma \vdash A)$  iff  $1 \in \eta(\Gamma \vdash A)$ , i.e.  $\eta(\Gamma) \subset \eta(A)$ , **P**  $\models (\Gamma \vdash A)$  iff for every valuation  $\eta: \mathbf{P}, \eta \models (\Gamma \vdash A)$ ,  $\models (\Gamma \vdash A)$  iff for every phase space  $\mathbf{P}: \mathbf{P} \models (\Gamma \vdash A)$ .

This semantics of ILL formulas enjoys the following main properties:

**Theorem 4.5 (Soundness [10, 24])** If there is a sequent calculus proof of  $\Gamma \vdash A$  then  $\models (\Gamma \vdash A)$ .

**Theorem 4.6 (Completeness [10, 24])** *If*  $\models$  ( $\Gamma \vdash A$ ) *then there is a sequent calculus proof of*  $\Gamma \vdash A$ .

## 4.2 Proving safety properties of LCC programs with the phase semantics

Using the phase semantics presented above we will now prove safety properties of CC programs. We use the soundness of the translation from LCC into ILL and so require, either to translate CC programs into LCC or to write programs directly in LCC.

The theorem 4.5 of soundness of the phase semantics w.r.t. ILL is:

 $\Gamma \vdash_{ILL} A \text{ implies } \forall P, \eta, P, \eta \models (\Gamma \vdash A).$ 

It can easily be extended to  $ILL_{\mathcal{C},\mathcal{D}}$  by imposing to any valuation  $\eta$  to satisfy the inclusions coming from the non-logical axioms (the axiom  $c \vdash d$  imposes  $\eta(c) \subset \eta(d)$ ).

By contrapositive we get:

 $\exists P, \eta, \text{ s.t. } P, \eta \not\models (\Gamma \vdash A) \text{ implies } \Gamma \not\vdash_{ILL_{\mathcal{C}} \mathcal{D}} A,$ 

which is equivalent to:

$$\exists P, \eta, \text{ s.t. } \eta(\Gamma) \not\subset \eta(A) \text{ implies } \Gamma \not\vdash_{ILL_{\mathcal{C},\mathcal{D}}} A.$$

As the contrapositive of the theorem 3.7 of soundness from LCC to  $ILL_{\mathcal{C},\mathcal{D}}$  is:

 $(\vec{x};c;\Gamma)^{\dagger} \not\vdash_{ILL_{\mathcal{C},\mathcal{D}}} (\vec{y};d;\Delta)^{\dagger} \text{ implies } (\vec{x};c;\Gamma) \not\rightarrow_{LCC} (\vec{y};d;\Delta)$ 

We have:

**Proposition 4.7** To prove a safety property of the kind:  $(\vec{x}; c; \Gamma) \not\rightarrow_{LCC} (\vec{y}; d; \Delta)$ , it is enough to show that:

 $\exists$  a phase space  $\mathbf{P}$ , a valuation  $\eta$ , and an element  $a \in \eta((\vec{x}; c; \Gamma)^{\dagger})$  such that  $a \notin \eta((\vec{y}; d; \Delta)^{\dagger})$ .

This proposition allows to reduce the problem of proving safety properties of CC programs, i.e. proving the non-existence of some derivation, to an existence problem: finding a phase structure, an interpretation and a counter-example for the above inclusion, or even, only proving their existence. Note that only soundness theorems are used, the second part of the correspondence (completeness) gives a certain certitude that when looking for a semantical proof of a true safety property, it exists!

#### 4.3 Example 1 - Dining philosophers

As shown in section 2.2 the dining philosophers problem can easily be encoded in LCC. Let us try to prove, for instance, that this encoding satisfies the safety property that it does not allow two philosophers to eat with the same fork at the same time, independently of the number of philosophers.

i) **Reformulating the property.** We first have to express that we don't want two neighbors to eat together in a safety property of the above form:

```
\forall \mathbb{N}, \forall \mathbb{I}, \forall c, \forall A, (\emptyset; 1; \texttt{init}(\mathbb{N})) \not \rightarrow_{LCC} (\emptyset; \texttt{eat}(\mathbb{I}), \texttt{eat}(\mathbb{I}+1 \mod \mathbb{N}), c; A)
```

From the corollary, it is enough to show:

 $\forall \mathtt{N}, \forall \mathtt{I}, \exists P, \exists \eta, \exists x \in \eta(\mathtt{init}(\mathtt{N})), x \notin \eta(\mathtt{eat}(\mathtt{I}) \otimes \mathtt{eat}(\mathtt{I+1} \mod \mathtt{N}) \otimes \top)$ 

where  $\top$  is the usual constant of linear logic that means "anything" and so can replace c and A for any c and any A.

ii) Phase space. Consider the following structure P:

- $\mathbb{N}$  (with it's usual product and unit) is the monoid,
- $\mathcal{F} = \mathcal{P}(\mathbb{N}),$
- $O = \{\emptyset, \{1\}\}.$

It is definitely a phase structure.

iii) Valuation. We need to define a valuation  $\eta$  on fork(I), eat(I,N), N=M, N $\neq$ M, philosopher(I,N), recphilo(M,P) and init(N). We must not forget to check that the conditions coming from the declarations (non-logical axioms which translate into compulsory inclusions) of philosopher(I,N), recphilo(M,P) and init(N) are satisfied.

Let us define  $\eta$  as follows:

$\eta(\texttt{fork(I)}) = \{f_i\}$ $\eta(\texttt{eat(I,N)}) = \{e_{i,n}\}$	$\eta(\mathbf{N})$	1 =	$M) = \left\{ {} \right.$	${1} \\ \emptyset$	$ \begin{array}{l} \text{if } n = m, \\ otherwise, \end{array} $
$\eta(\text{philosopher}(I,N)) = \{p_i\} \\ \eta(\text{recphilo}(M,P)) = \{x_{m,p} \cdot y_{m,p}\} \\ \eta(\text{init}(N)) = \{x_{1,n} \cdot y_{1,n}\}$	$\eta({ t N}$	i ≠	$M) = \begin{cases} \\ \\ \end{cases}$	${1} \\ \emptyset$	if $n \neq m$ , otherwise,

where the indices (i, m, n, p) are the canonical interpretation of the corresponding integer variables,  $f_i$  and  $p_i$  are distinct prime numbers, and  $e_i, x_{m,p}$ 

and  $y_{m,p}$  are defined as follows:

$$e_{i,n} = f_i \cdot f_{i+1 \mod n} \cdot p_i$$

$$\begin{array}{lll} x_{m,p} & = & \left\{ \begin{array}{ll} 1 & \text{if } m = p, \\ p_m \cdot f_m \cdot x_{m+1,p} \cdot y_{m+1,p} & \text{otherwise.} \end{array} \right. \\ y_{m,p} & = & \left\{ \begin{array}{ll} p_m \cdot f_m & \text{if } m = p, \\ 1 & \text{otherwise.} \end{array} \right. \end{array}$$

The conditions coming from the declarations are:

 $\begin{aligned} &-\forall i, \{p_i\} \subset E_{i,n} \text{ where } E_{i,n} = \eta(\text{body of philosopher(I,N)}) \\ &-\forall m, \forall p, \{x_{m,p} \cdot y_{m,p}\} \subset F_{m,p} \text{ where } F_{m,p} = \eta(\text{body of recphilo(M,P)}) \\ &-\forall n, \{x_{1,n} \cdot y_{1,n}\} \subset \eta(\text{body of init(N)}). \end{aligned}$ 

One can easily notice that the third condition is implied by the second one. Remembering that an agent  $A \longrightarrow_{LCC} B \longrightarrow_{LCC} C \longrightarrow_{LCC} D$  is interpreted as  $\{x \in \mathbb{N} : \forall y \in \eta(A), \forall z \in \eta(B), \forall t \in \eta(C), \exists u \in \eta(D), x \cdot y \cdot z \cdot t = u\}$ , we can deduce:  $E_{i,n} = \{x \in \mathbb{N} : \exists y \in G_{i,n}, f_{i+1 \mod n} \cdot f_i \cdot x = e_{i,n} \cdot y\}$ with  $G_{i,n} = \{y \in \mathbb{N} : e_{i,n} \cdot y = f_i \cdot f_{i+1 \mod n} \cdot p_i\}$ 

(y represents an element of the interpretation of the part  $eat(I,N) \rightarrow (tell(fork(I) \otimes fork(I+1 \mod N)) \parallel philosopher(I,N))$  in the I<sup>th</sup> philosopher).

Now, observe that the first condition  $\forall i, \{p_i\} \subset E_{i,n}$  reduces to show that  $G_{i,n}$  is non-empty, which is true as  $1 \in G_{i,n}$ . The second condition on  $F_{m,p}$  is verified with a simple induction on  $x_{m,p}$  and  $y_{m,p}$  which have been defined on purpose. The valuation is thus correct.

iv) Counter-example. As  $\eta(\text{init}(\mathbb{N})) = \{x_{1,n} \cdot y_{1,n}\}$  we must prove:  $x_{1,n} \cdot y_{1,n} \notin \eta(\text{eat}(\mathbb{I},\mathbb{N}) \otimes \text{eat}(\mathbb{I}+1 \mod \mathbb{N},\mathbb{N}) \otimes \top) =$ 

 $\{x \in \mathbb{N} : \exists a \in \mathbb{N}, x = e_{i,n} \cdot e_{i+1 \mod n, n} \cdot a\}.$ 

First we show by induction that:  $x_{1,n} \cdot y_{1,n} = f_1 \cdot \ldots \cdot f_n \cdot p_1 \cdot \ldots \cdot p_n$ And then proceed *Ab absurdum*:

if  $x_{1,n} \cdot y_{1,n} = e_{i,n} \cdot e_{i+1 \mod n,n} \cdot a$  then

$$f_{i+1 \mod n} \cdot x_{1,n} \cdot y_{1,n} = e_{i,n} \cdot e_{i+1 \mod n,n} \cdot a \cdot f_{i+1 \mod n}$$
$$= f_1 \cdot \ldots \cdot f_{i-1} \cdot f_{i+3} \cdot \ldots \cdot f_n \cdot$$
$$p_1 \cdot \ldots \cdot p_{i-1} \cdot p_{i+2} \cdot \ldots \cdot p_n \cdot e_{i,n} \cdot e_{i+1 \mod n,n}$$

hence, simplifying we get

$$a \cdot f_{i+1 \mod n} = f_1 \cdot \ldots \cdot f_{i-1} \cdot f_{i+3} \cdot \ldots \cdot f_n \cdot p_1 \cdot \ldots \cdot p_{i-1} \cdot p_{i+2} \cdot \ldots \cdot p_n$$

which is impossible (prime factors decomposition:  $f_{i+1 \mod n}$  appears on the left hand of = but not on the right hand, a product of prime numbers), qed.

#### Remark:

- It is worth noting that, although a similar soundness theorem holds for the translation of agents into intuitionistic logic (IL), if we use that translation instead of ILL we will not be able to prove anything because from philosopher(I)  $\land$  fork(I)  $\land$  fork(I+1)  $\vdash$  eat(I,N) and philosopher(I+1)  $\land$  fork(I+1)  $\land$  fork(I+2)  $\vdash$  eat(I+1,N)we can infer philosopher(I)  $\land$  philosopher(I+1)  $\land$  fork(I)  $\land$  fork(I)  $\land$  fork(I)  $\land$  fork(I+1)  $\vdash$  fork(I+1)  $\land$  fork(I+2)  $\vdash$  eat(I,N)  $\land$  fork(I+2)  $\vdash$  eat(I,N)  $\land$  eat(I+1,N).

- The phase structure might seem unnatural, but in this case it can be simply considered as the free commutative monoid built on the atomic constraints of the program, interpreted as singletons, and generated by the equalities coming from the non-logical axioms (i.e. inclusions between singletons). Such a singleton-based phase structure cannot always be used however. For instance with the following program:  $P = tell(d), Q = c \rightarrow P$ , a singleton-based phase structure does not allow one to prove that c is not accessible from P, i.e.  $P \nvDash c \otimes T$ , as we can deduce  $\eta(P) = c \cdot \eta(Q)$  from the second declaration.

#### 4.4 Example 2 - Producer/Consumer

The producer/consumer protocol with m producers and k consumers communicating via a buffer of size n can be encoded in LCC as follows:

 $\begin{array}{l} \texttt{P} = \texttt{dem} \rightarrow (\texttt{pro} \parallel \texttt{P}) \\ \texttt{C} = \texttt{pro} \rightarrow (\texttt{dem} \parallel \texttt{C}) \\ \texttt{init} = \texttt{dem}^n \parallel \texttt{P}^m \parallel \texttt{C}^k \end{array}$ 

Let us prove, with the same phase structure as above, that this protocol, encoded this way, is deadlock free, and safe (the number of units consumed is always less than the number of units produced).

#### 4.4.1 Deadlock Freeness

The first task is to state this safety property in the form  $(\vec{x}; c; \Gamma) \xrightarrow{} UCC$  $(\vec{y}; d; \Delta)$ . One can easily see that a deadlock may only occur if there is, either no P left, or no C left, or nothing to consume (dem and pro).

i) We thus want to prove init  $\neq \perp_{LCC} \operatorname{dem}^{n'} \parallel \mathbb{P}^{m'} \parallel \mathbb{C}^{k'} \parallel \operatorname{pro}^{l'}$ , with either n' = l' = 0 or m' = 0 or k' = 0.

ii) Let us now consider the structure  $P = \mathbb{N}$ ,  $\mathcal{F} = \mathcal{P}(\mathbb{N})$ , and  $O = \{\emptyset, \{1\}\}$ , it is obviously a phase structure.

iii) Let us define the following valuation:

$$\begin{split} \eta(\texttt{dem}) &= \{5\} \ \eta(\texttt{pro}) = \{5\} \ \eta(\texttt{P}) = \{2\} \ \eta(\texttt{C}) = \{3\} \\ \eta(\texttt{init}) &= \{2^m \cdot 3^k \cdot 5^n\} \end{split}$$

We have to check the correctness of  $\eta$ :  $\forall p_1 \in \eta(\mathsf{P}), \exists p_2 \in \eta(\mathsf{P}), dem \cdot p_1 = pro \cdot p_2$ , hence  $\eta(\mathsf{P}) \subset \eta(\text{body of }\mathsf{P})$ . The same for C, and  $\eta(\texttt{init}) = \eta(\texttt{body of init})$ .

iv) Instead of exhibiting a counter-example, we will again prove Ab absurdum that the inclusion  $\eta(\texttt{init}) \subset \eta(\texttt{dem}^{n'} || \mathsf{P}^{m'} || \mathsf{C}^{k'} || \texttt{pro}^{l'})$  is impossible. Suppose  $\eta(\texttt{init}) \subset \{5^{n'} \cdot 2^{m'} \cdot 3^{k'} \cdot 5^{l'}\}$  Comparing the power of 5, 3 and

Suppose  $\eta(\texttt{init}) \subset \{5^{n'} \cdot 2^{m'} \cdot 3^{k'} \cdot 5^{l'}\}$  Comparing the power of 5, 3 and 2, anything else than: n' + l' = n and m' = m and k' = k is impossible, and therefore if there is a deadlock  $(n' + l' = 0 \neq n, \text{ or } m' = 0 \neq m, \text{ or } k' = 0 \neq k)$  $\eta(\texttt{init})$  is not a subset of its interpretation and thus init does not reduce into it, qed.

#### 4.4.2 Safety

In order to check that there are never more units consumed than units produced, the encoding must be slightly modified to make this information directly observable:

$$\begin{array}{l} \texttt{P} = \texttt{dem} \rightarrow (\texttt{pro} \parallel \texttt{P} \parallel \forall \texttt{X} (\texttt{np=X} \rightarrow \texttt{np=X+1})) \\ \texttt{C} = \texttt{pro} \rightarrow (\texttt{dem} \parallel \texttt{C} \parallel \forall \texttt{X} (\texttt{nc=X} \rightarrow \texttt{nc=X+1})) \\ \texttt{init} = \texttt{dem}^n \parallel \texttt{P}^m \parallel \texttt{C}^k \parallel \texttt{np=0} \parallel \texttt{nc=0} \end{array}$$

This kind of modification, namely adding an "oracle" to observe the property of interest, is commonly seen in other verification techniques, for instance when adding a separate automaton in model checking.

```
i) We want to prove:
```

 $\begin{array}{c} \operatorname{init} \xrightarrow{} \to_{LCC} \operatorname{dem}^{n'} \parallel \operatorname{pro}^{l'} \parallel \operatorname{P}^{m} \parallel \operatorname{C}^{k} \parallel \operatorname{np=np}_{0} \parallel \operatorname{nc=nc}_{0} \\ \operatorname{with} \operatorname{nc}_{0} > \operatorname{np}_{0}. \end{array}$ 

ii) Once again we can use a quite simple structure,  $P = \mathbb{Q}, \mathcal{F} = \mathcal{P}(\mathbb{Q}), O = \{\emptyset, \{1\}\}.$ 

iii) And the following valuation:

$$\eta(\texttt{dem}) = \{6\} \ \eta(\texttt{pro}) = \{3\} \ \eta(\texttt{P}) = \{5\} \ \eta(\texttt{C}) = \{7\}$$
$$\eta(\texttt{np=X}) = \{2^x\} \ \eta(\texttt{nc=X}) = \{2^{-x}\}$$
$$\eta(\texttt{init}) = \{2^n \cdot 3^n \cdot 5^m \cdot 7^k\}$$

This valuation is correct:  $\exists d = 2 \text{ s.t. } dem \cdot p = pro \cdot p \cdot d \text{ and } \forall x, 2^x \cdot d = 2^{x+1}$ hence  $\eta(\mathbf{P}) \subset \eta(\text{body of } \mathbf{P}).$ 

iv) Now, It suffices to remark that  $nc_0 > np_0$  and  $\eta(init) \subset \{6^{n'} \cdot 3^{l'} \cdot 5^m \cdot 7^k \cdot 2^{np_0} \cdot 2^{-nc_0}\}$  would imply l' < 0, which is impossible, ged.

#### 4.5 Example 3 - Mutual exclusion

There is no ";" (sequentiality operator) in the syntax, but it can be added without losing the soundness properties by translating it as " $\otimes$ " (similarly, the guarded choice can be translated as "&"). The following example of mutual exclusion with semaphores shows an example of LCC + ";" program on which one can prove safety properties:

i) We want to prove that the two critical sections cs cannot take place at the same time:  $\forall B$ , init  $\rightarrow_{LCC} cs \parallel cs \parallel B$  i.e.  $init^{\ddagger} \not\vdash cs \otimes cs \otimes \top$ .

ii, iii, iv) The structure  $P = \mathbb{N}$  and the valuation  $\eta(\texttt{sem}) = \eta(\texttt{cs}) = \eta(\texttt{init}) = \{2\}$  and  $\eta(\texttt{A}) = \eta(\texttt{P}_i) = \{1\}$  are correct. The proof of existence of a counterexample (again *ab absurdum*) is trivial.

This handling of ";", or of the guarded choice, may be quite surprising and is of course not general. It shows that although these operators have no simple logical interpretation, it is nevertheless sometimes possible to capture their operational behavior in the statement of the property. In the previous example it was enough to show  $\forall B$ , init  $\rightarrow_{LCC} \operatorname{cs} \parallel \operatorname{cs} \parallel B$  because we know that **A** is over when we remove cs from the store; showing  $\forall B$ , init  $\rightarrow_{LCC} \operatorname{A} \parallel \operatorname{A} \parallel B$ would not be possible by interpreting ";" as " $\otimes$ ".

#### 5 Conclusion and perspectives

Building upon the close correspondence between CC executions and proof search in LL, we have shown that the semantics of provability (not of proofs) in LL provides an interesting level of abstraction for reasoning about CC programs, getting rid of unnecessary execution details. In particular we have shown that various safety properties of simple protocol CC programs could be proved directly, simply by exhibiting a phase space and an interpretation of the program in which the property holds.

These results open also a lot of questions, for instance on the shape of the simplest phase spaces for proving a given safety property, and on the possibility of automatizing such "semantical" proofs in a somewhat similar way to model checking. These issues should serve further investigation.

The method can be generalized to handle more safety properties of LCC programs. In particular the characterization of LCC suspensions [28] in the non-commutative logic of the second author [27], can be used to prove deadlock properties using non-commutative phase spaces.

The extension – induced by the logic – of CC languages to linear constraint systems is also interesting to study in its own right as it reconciles declarative programming with some form of imperative programming. We have shown this on simple examples for protocol specification. As another example, the rationale reconstruction of CLP(FD) constraint propagators by CC agents given in [11] could be extended in LCC to cover the propagation algorithms of *global constraints* which use imperative (backtrackable) data structures. Such a logical reconstruction with LCC would be thus more faithful to current CLP(FD) practice.

#### Acknowledgments

We are particularly grateful to Dale Miller, Catuscia Palamidessi and Vijay Saraswat for fruitful discussions on this work.

#### A Appendix: Intuitionistic linear sequent calculus

**Definition A.1 (Intuitionistic formulas)** The intuitionistic formulas are built from atoms  $p, q, \ldots$  with:

- the multiplicative connectives:  $\otimes$  (tensor) and implication  $\multimap$ ,
- the additive connectives: & (with) and  $\oplus$  (plus),
- the exponential connective ! (of course or bang),
- the constants: multiplicative 1 and  $\perp$ , and additive  $\top$  and 0,
- the quantifiers: universal  $\forall$  and existential  $\exists$ .

**Definition A.2 (Intuitionistic sequents)** The sequents are of the form  $\Gamma \vdash A$  or  $\Gamma \vdash$ , where A is a formula and  $\Gamma$  is a multiset of formulas.

The sequent calculus is given by the following rules:

Axiom - Cut

$$A \vdash A \qquad \frac{\Gamma \vdash A \quad \Delta, A \vdash B}{\Delta, \Gamma \vdash B}$$

Multiplicatives

$$\begin{array}{c} \Gamma, A, B \vdash C \\ \hline \Gamma, A \otimes B \vdash C \end{array} \qquad \qquad \begin{array}{c} \Gamma \vdash A & \Delta \vdash B \\ \hline \Delta, \Gamma \vdash A \otimes B \\ \hline \end{array} \\ \hline \begin{array}{c} \Gamma \vdash A \\ \hline \Delta, \Gamma, A \multimap B \vdash C \end{array} \qquad \qquad \begin{array}{c} \Gamma \vdash A \\ \hline \end{array} \\ \hline \begin{array}{c} \Gamma, A \vdash B \\ \hline \Gamma \vdash A \multimap B \end{array} \end{array}$$

Additives

$$\begin{array}{c|c} \hline \Gamma, A \vdash C & \Gamma, B \vdash C \\ \hline \Gamma, A \oplus B \vdash C & \hline \Gamma \vdash A \oplus B & \hline \Gamma \vdash A \oplus B \\ \hline \hline \Gamma \vdash A \oplus B & \hline \Gamma \vdash A \oplus B & \hline \Gamma \vdash A \oplus B \\ \hline \hline \Gamma \vdash A \& B & \hline \Gamma, A \& B \vdash C & \hline \Gamma, A \& B \vdash C \\ \hline \hline \hline \Gamma, A \& B \vdash C & \hline \hline \Gamma, A \& B \vdash C & \hline \hline \hline \Gamma, A \& B \vdash C \\ \hline \end{array}$$

#### Constants

$$\frac{\Gamma \vdash A}{\Gamma, \mathbf{1} \vdash A} \vdash \mathbf{1} \qquad \bot \vdash \qquad \frac{\Gamma \vdash}{\Gamma \vdash \bot} \qquad \Gamma \vdash \top \qquad \Gamma, \mathbf{0} \vdash A$$

## Bang

$$\frac{\Gamma, A \vdash B}{\Gamma, !A \vdash B} \qquad \frac{!\Gamma \vdash A}{!\Gamma \vdash !A}$$
$$\frac{\Gamma, !A, !A \vdash B}{\Gamma, !A \vdash B} \qquad \frac{\Gamma \vdash B}{\Gamma, !A \vdash B}$$

## Quantifiers

$$\frac{\Gamma, A[t/x] \vdash B}{\Gamma, \forall xA \vdash B} \qquad \qquad \frac{\Gamma \vdash A}{\Gamma \vdash \forall xA} x \notin fv(\Gamma)$$
$$\frac{\Gamma, A \vdash B}{\Gamma, \exists xA \vdash B} x \notin fv(\Gamma, B) \qquad \qquad \frac{\Gamma \vdash A[t/x]}{\Gamma \vdash \exists xA}$$
