

Abstract Interpretation III

Semantics and Application to Program Verification

Antoine Miné

École normale supérieure, Paris
year 2013–2014

Course 11

14 May 2014

- Last week: **non-relational abstract domains** (intervals)
abstract each variable independently from the others
can express important properties (e.g., absence of overflow)
unable to represent relations between variables
- **This week: relational abstract domains**
more precise, but more costly
 - the need for relational domains
 - **linear equality** domain $(\sum_i \alpha_i V_i = \beta_i)$
 - **polyhedra** domain $(\sum_i \alpha_i V_i \geq \beta_i)$
 - project: relational analysis with the **Apron** library
- Next week: selected advanced topics on abstract domains
(not needed for the project)

Motivation

Relational assignments and tests

Example

```

 $X \leftarrow \text{rand}(0, 10); Y \leftarrow \text{rand}(0, 10);$ 
if  $X > Y$  then  $X \leftarrow Y$  else skip;
 $D \leftarrow Y - X;$ 
assert  $D \geq 0$ 

```

Interval analysis:

- $S^\sharp \llbracket X > Y? \rrbracket$ is abstracted as the **identity**
 given $R^\sharp \stackrel{\text{def}}{=} [X \mapsto [0, 10], Y \mapsto [0, 10]]$
 $S^\sharp \llbracket \text{if } X > Y \text{ then } \dots \rrbracket R^\sharp = R^\sharp$
- $D \leftarrow Y - X$ gives $D \in [0, 10] -^\sharp [0, 10] = [-10, 10]$
- the assertion $D \geq 0$ **fails**

Relational assignments and tests

Example

```

 $X \leftarrow \text{rand}(0, 10); Y \leftarrow \text{rand}(0, 10);$ 
if  $X > Y$  then  $X \leftarrow Y$  else skip;
 $D \leftarrow Y - X;$ 
assert  $D \geq 0$ 

```

Solution: relational domain

- represent explicitly the information $X \leq Y$
- infer that $X \leq Y$ holds after the **if** \dots **then** \dots **else** \dots
 $X \leq Y$ both after $X \leftarrow Y$ when $X > Y$, and after **skip** when $X \leq Y$
- use $X \leq Y$ to deduce that $Y - X \in [0, 10]$

Note:

the **invariant** we seek, $D \geq 0$, can be exactly represented in the **interval** domain but **inferring** $D \geq 0$ requires a **more expressive** domain locally

Relational loop invariants

Example

```

I ← 1; X ← 0;
while I ≤ 1000 do
  I ← I + 1; X ← X + 1;
assert X ≤ 1000

```

Interval analysis:

- after iterations with **widening**, we get in 2 iterations:
 - as loop invariant: $I \in [1, +\infty]$ and $X \in [0, +\infty]$
 - after the loop: $I \in [1001, +\infty]$ and $X \in [0, +\infty] \implies$ **assert fails**
- using a **decreasing** iteration after widening, we get:
 - as loop invariant: $I \in [1, 1001]$ and $X \in [0, +\infty]$
 - after the loop: $I = 1001$ and $X \in [0, +\infty] \implies$ **assert fails**
 (the test $I \leq 1000$ only refines I , but gives no information on X)
- without widening, we get $I = 1001$ and $X = 1000 \implies$ **assert passes**
 but we need **1000 iterations!** (\simeq concrete fixpoint computation)

Relational loop invariants

Example

```

l ← 1; X ← 0;
while l ≤ 1000 do
    l ← l + 1; X ← X + 1;
assert X ≤ 1000
  
```

Solution: relational domain

- infer a **relational loop invariant**: $l = X + 1 \wedge 1 \leq l \leq 1001$
 - $l = X + 1$ holds before entering the loop as $1 = 0 + 1$
 - $l = X + 1$ is invariant by the loop body $l \leftarrow l + 1; X \leftarrow X + 1$
 - (can be inferred in 2 iterations with widening in the polyhedra domain)
- propagate the loop exit condition $l > 1000$ to get:
 - $l = 1001$
 - $X = l - 1 = 1000 \implies$ **assert** passes

Note:

the invariant we seek after the loop exit has an interval form: $X \leq 1000$
 but we need to infer a more **expressive loop invariant to deduce it**

Affine Equalities

The affine equality domain

We look for invariants of the form:

$$\wedge_j (\sum_{i=1}^n \alpha_{ij} V_i = \beta_j), \alpha_{ij}, \beta_j \in \mathbb{Q}$$

where all the α_{ij} and β_j are inferred automatically

We use a domain of affine spaces proposed by Karr in 1976

$$\mathcal{E}^\# \simeq \{ \text{affine subspaces of } \mathbb{V} \rightarrow \mathbb{R} \}$$

(with a suitable machine representation)

Affine equality representation

Machine representation:

$$\mathcal{E}^\# \stackrel{\text{def}}{=} \cup_m \{ \langle \mathbf{M}, \vec{\mathbf{C}} \rangle \mid \mathbf{M} \in \mathbb{Q}^{m \times n}, \vec{\mathbf{C}} \in \mathbb{Q}^m \} \cup \{\perp\}$$

- either the constant \perp
- or a pair $\langle \mathbf{M}, \vec{\mathbf{C}} \rangle$ where
 - $\mathbf{M} \in \mathbb{Q}^{m \times n}$ is a $m \times n$ matrix, $n = |\mathbb{V}|$ and $m \leq n$,
 - $\vec{\mathbf{C}} \in \mathbb{Q}^m$ is a row-vector with m rows

$\langle \mathbf{M}, \vec{\mathbf{C}} \rangle$ represents an equation system, with solutions:

$$\gamma(\langle \mathbf{M}, \vec{\mathbf{C}} \rangle) \stackrel{\text{def}}{=} \{ \vec{\mathbf{V}} \in \mathbb{R}^n \mid \mathbf{M} \times \vec{\mathbf{V}} = \vec{\mathbf{C}} \}$$

\mathbf{M} should be in **row echelon form**:

- $\forall i \leq m: \exists k_i: M_{ik_i} = 1$ and
 $\forall c < k_i: M_{ic} = 0, \forall l \neq i: M_{lk_i} = 0,$
- if $i < i'$ then $k_i < k_{i'}$ (leading index)

example:

$$\begin{bmatrix} 1 & 0 & 0 & 5 & 0 \\ 0 & 1 & 0 & 6 & 0 \\ 0 & 0 & 1 & 7 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Remarks:

the representation is unique

as $m \leq n = |\mathbb{V}|$, the memory cost is in $\mathcal{O}(n^2)$ at worst

\perp is represented as the empty equation system: $m = 0$

Galois connection

Galois connection:

(actually, a Galois insertion)

between arbitrary subsets and affine subsets

$$(\mathcal{P}(\mathbb{R}^{|\mathbb{V}|}), \subseteq) \xleftarrow{\gamma} \xrightarrow{\alpha} (\text{Aff}(\mathbb{R}^{|\mathbb{V}|}), \subseteq)$$

- $\gamma(X) \stackrel{\text{def}}{=} X$ (identity)
- $\alpha(X) \stackrel{\text{def}}{=} \text{smallest affine subset containing } X$

$\text{Aff}(\mathbb{R}^{|\mathbb{V}|})$ is closed under arbitrary intersections, so we have:

$$\alpha(X) = \bigcap \{ Y \in \text{Aff}(\mathbb{R}^{|\mathbb{V}|}) \mid X \subseteq Y \}$$

$\text{Aff}(\mathbb{R}^{|\mathbb{V}|})$ contains every point in $\mathbb{R}^{|\mathbb{V}|}$

we can also construct $\alpha(X)$ by (abstract) union:

$$\alpha(X) = \bigcup^{\#} \{ \{x\} \mid x \in X \}$$

Notes:

- we have assimilated $\mathbb{V} \rightarrow \mathbb{R}$ to $\mathbb{R}^{|\mathbb{V}|}$
- we have used $\text{Aff}(\mathbb{R}^{|\mathbb{V}|})$ instead of the matrix representation $\mathcal{E}^{\#}$ for simplicity; a Galois connection also exists between $\mathcal{P}(\mathbb{R}^{|\mathbb{V}|})$ and $\mathcal{E}^{\#}$

Normalisation and emptiness testing

Let $\mathbf{M} \times \vec{V} = \vec{C}$ be a system, not necessarily in normal form

The **Gaussian reduction** tells in $\mathcal{O}(n^3)$ time:

- whether the system is satisfiable, and in that case
- gives an equivalent system in normal form

i.e.: it returns an element in \mathcal{E}^\sharp

Example:

$$\left\{ \begin{array}{rclcl} 2X & + & Y & + & Z & = & 19 \\ 2X & + & Y & - & Z & = & 9 \\ & & & & 3Z & = & 15 \end{array} \right.$$

\Downarrow

$$\left\{ \begin{array}{rclcl} X & + & 0.5Y & & & = & 7 \\ & & & & Z & = & 5 \end{array} \right.$$

Normalisation and emptiness testing (cont.)

Gaussian reduction algorithm: *Gauss*($\langle \mathbf{M}, \vec{C} \rangle$)

```

 $r \leftarrow 0$  (rank  $r$ )
for  $c$  from 1 to  $n$  (column  $c$ )
  if  $\exists \ell > r: M_{\ell c} \neq 0$  (pivot  $\ell$ )
     $r \leftarrow r + 1$ 
    swap  $\langle \vec{M}_\ell, C_\ell \rangle$  and  $\langle \vec{M}_r, C_r \rangle$ 
    divide  $\langle \vec{M}_r, C_r \rangle$  by  $M_{rc}$ 
    for  $j$  from 1 to  $n, j \neq r$ 
      replace  $\langle \vec{M}_j, C_j \rangle$  with  $\langle \vec{M}_j, C_j \rangle - M_{jc} \langle \vec{M}_r, C_r \rangle$ 
  if  $\exists \ell: \langle \vec{M}_\ell, C_\ell \rangle = \langle 0, \dots, 0, c \rangle, c \neq 0$ 
    then return  $\perp$ 
remove all rows  $\langle \vec{M}_\ell, C_\ell \rangle$  that equal  $\langle 0, \dots, 0, 0 \rangle$ 

```

Affine equality operators

Abstract operators:

If $X^\sharp, Y^\sharp \neq \perp$, we define:

$$X^\sharp \cap^\sharp Y^\sharp \stackrel{\text{def}}{=} \text{Gauss} \left(\left\langle \left[\begin{array}{c} \mathbf{M}_{X^\sharp} \\ \mathbf{M}_{Y^\sharp} \end{array} \right], \left[\begin{array}{c} \vec{c}_{X^\sharp} \\ \vec{c}_{Y^\sharp} \end{array} \right] \right\rangle \right) \quad (\text{join equations})$$

$$X^\sharp =^\sharp Y^\sharp \stackrel{\text{def}}{\iff} \mathbf{M}_{X^\sharp} = \mathbf{M}_{Y^\sharp} \quad \text{and} \quad \vec{c}_{X^\sharp} = \vec{c}_{Y^\sharp} \quad (\text{uniqueness})$$

$$X^\sharp \subseteq^\sharp Y^\sharp \stackrel{\text{def}}{\iff} X^\sharp \cap^\sharp Y^\sharp =^\sharp X^\sharp$$

$$S^\sharp[\sum_j \alpha_j V_j = \beta?] X^\sharp \stackrel{\text{def}}{=} \text{Gauss} \left(\left\langle \left[\begin{array}{c} \mathbf{M}_{X^\sharp} \\ \alpha_1 \cdots \alpha_n \end{array} \right], \left[\begin{array}{c} \vec{c}_{X^\sharp} \\ \beta \end{array} \right] \right\rangle \right) \quad (\text{add equation})$$

$$S^\sharp[e \bowtie e'?] X^\sharp \stackrel{\text{def}}{=} X^\sharp \quad \text{for other tests}$$

Remark:

$\subseteq^\sharp, =^\sharp, \cap^\sharp, =^\sharp$ and $S^\sharp[\sum_j \alpha_j V_j - \beta = 0?]$ are **exact**:

$$(X^\sharp \subseteq^\sharp Y^\sharp \iff \gamma(X^\sharp) \subseteq \gamma(Y^\sharp), \quad \gamma(X^\sharp \cap^\sharp Y^\sharp) = \gamma(X^\sharp) \cap \gamma(Y^\sharp), \dots)$$

Affine equality assignment

Non-deterministic assignment: $S^\# [V_j \leftarrow [-\infty, +\infty]]$

Principle: remove **all** the occurrences of V_j
but reduce the number of equations by only **one**
(add a single degree of freedom)

Algorithm: assuming V_j occurs in \mathbf{M}

- Pick the row $\langle \vec{M}_i, C_i \rangle$ such that $M_{ij} \neq 0$ and i **maximal**
- Use it to **eliminate** all the occurrences of V_j in lines before i
(i maximal $\implies \mathbf{M}$ stays in row echelon form)
- Remove the row $\langle \vec{M}_i, C_i \rangle$

Example: forgetting Z

$$\begin{cases} X + Z = 10 \\ Y + Z = 7 \end{cases} \implies \begin{cases} X - Y = 3 \end{cases}$$

The operator is **exact**

Affine equality assignment

Affine assignments: $S^\# [V_j \leftarrow \sum_i \alpha_i V_i + \beta]$

$$S^\# [V_j \leftarrow \sum_i \alpha_i V_i + \beta] X^\# \stackrel{\text{def}}{=} X^\#$$

if $\alpha_j = 0$, $(S^\# [V_j = \sum_i \alpha_i V_i + \beta?] \circ S^\# [V_j \leftarrow [-\infty, +\infty]]) X^\#$

if $\alpha_j \neq 0$, $\langle \mathbf{M}, \vec{C} \rangle$ where V_j is replaced with $\frac{1}{\alpha_j} (V_j - \sum_{i \neq j} \alpha_i V_i - \beta)$
(variable substitution)

Proof sketch: based on properties in the concrete

non-invertible assignment: $\alpha_j = 0$

$S [V_j \leftarrow e] = S [V_j \leftarrow e] \circ S [V_j \leftarrow [-\infty, +\infty]]$ as the value of V is not used in e
so $S [V_j \leftarrow e] = S [V_j = e?] \circ S [V_j \leftarrow [-\infty, +\infty]]$

invertible assignment: $\alpha_j \neq 0$

$S [V_j \leftarrow e] \subsetneq S [V_j \leftarrow e] \circ S [V_j \leftarrow [-\infty, +\infty]]$ as e depends on V

$$\begin{aligned} \rho \in S [V_j \leftarrow e] R &\iff \exists \rho' \in R: \rho = \rho' [V_j \mapsto \sum_i \alpha_i \rho'(V_i) + \beta] \\ &\iff \exists \rho' \in R: \rho [V_j \mapsto (\rho(V_j) - \sum_{i \neq j} \alpha_i \rho'(V_i) - \beta) / \alpha_j] = \rho' \\ &\iff \rho [V_j \mapsto (\rho(V_j) - \sum_{i \neq j} \alpha_i \rho(V_i) - \beta) / \alpha_j] \in R \end{aligned}$$

Non-affine assignments: revert to non-deterministic case

$$S^\# [V_j \leftarrow e] X^\# \stackrel{\text{def}}{=} S^\# [V_j \leftarrow [-\infty, +\infty]] X^\# \quad (\text{imprecise but sound})$$

Affine equality join

Join: $\langle \mathbf{M}, \vec{C} \rangle \cup^\# \langle \mathbf{N}, \vec{D} \rangle$

Idea: unify columns 1 to n of $\langle \mathbf{M}, \vec{C} \rangle$ and $\langle \mathbf{N}, \vec{D} \rangle$
using row operations

Example:

Assume that we have unified columns 1 to k to get $\begin{pmatrix} \mathbf{R} \\ \mathbf{0} \end{pmatrix}$, arguments are in row echelon form, and we have to unify at column $k+1$: ${}^t(\vec{0} \ 1 \ \vec{0})$ with ${}^t(\vec{\beta} \ 0 \ \vec{0})$

$$\left(\begin{array}{c} \mathbf{R} \ \vec{0} \ \mathbf{M}_1 \\ \vec{0} \ 1 \ \vec{M}_2 \\ \mathbf{0} \ \vec{0} \ \mathbf{M}_3 \end{array} \right), \left(\begin{array}{c} \mathbf{R} \ \vec{\beta} \ \mathbf{N}_1 \\ \vec{0} \ 0 \ \vec{N}_2 \\ \mathbf{0} \ \vec{0} \ \mathbf{N}_3 \end{array} \right) \Rightarrow \left(\begin{array}{c} \mathbf{R} \ \vec{\beta} \ \mathbf{M}'_1 \\ \vec{0} \ 0 \ \vec{0} \\ \mathbf{0} \ \vec{0} \ \mathbf{M}_3 \end{array} \right), \left(\begin{array}{c} \mathbf{R} \ \vec{\beta} \ \mathbf{N}_1 \\ \vec{0} \ 0 \ \vec{N}_2 \\ \mathbf{0} \ \vec{0} \ \mathbf{N}_3 \end{array} \right)$$

Use the row $(\vec{0} \ 1 \ \vec{M}_2)$ to create $\vec{\beta}$ in the left argument

Then remove the row $(\vec{0} \ 1 \ \vec{M}_2)$

The right argument is unchanged

\Rightarrow we have now unified columns 1 to $k+1$

Unifying ${}^t(\vec{\alpha} \ 0 \ \vec{0})$ and ${}^t(\vec{0} \ 1 \ \vec{0})$ is similar

Unifying ${}^t(\vec{\alpha} \ 0 \ \vec{0})$ and ${}^t(\vec{\beta} \ 0 \ \vec{0})$ is a bit more complicated...

No other case possible as we are in row echelon form

Analysis example

No infinite increasing chain: we can iterate **without widening!**

Example

```

X ← 10; Y ← 100;
while X ≠ 0 do
  X ← X - 1;
  Y ← Y + 10
  
```

Abstract loop iterations: $\lim \lambda X^\# . I^\# \cup^\# S^\# \llbracket \text{body} \rrbracket (S^\# \llbracket X \neq 0? \rrbracket X^\#)$

- loop entry: $I^\# = (X = 10 \wedge Y = 100)$
- after one loop body iteration: $F^\#(I^\#) = (X = 9 \wedge Y = 110)$
- $\implies X^\# \stackrel{\text{def}}{=} I^\# \cup^\# F^\#(I^\#) = (10X + Y = 200)$
- $X^\#$ is stable

at loop exit, we get $S^\# \llbracket X = 0? \rrbracket (10X + Y = 200) = (X = 0 \wedge Y = 200)$

Polyhedra

The polyhedron domain

We look for invariants of the form: $\bigwedge_j (\sum_{i=1}^n \alpha_{ij} V_i \geq \beta_j)$

We use the polyhedron domain by Cousot and Halbwachs (1978)

$$\mathcal{E}^\# \simeq \{ \text{closed convex polyhedra of } \mathbb{V} \rightarrow \mathbb{R} \}$$

Note: polyhedra need not be bounded (\neq polytopes)

Double description of polyhedra

Polyhedra have **dual** representations (Weyl–Minkowski Theorem)

Constraint representation

$\langle \mathbf{M}, \vec{C} \rangle$ with $\mathbf{M} \in \mathbb{Q}^{m \times n}$ and $\vec{C} \in \mathbb{Q}^m$

represents: $\gamma(\langle \mathbf{M}, \vec{C} \rangle) \stackrel{\text{def}}{=} \{ \vec{V} \mid \mathbf{M} \times \vec{V} \geq \vec{C} \}$

We will also often use a **constraint set notation** $\{ \sum_i \alpha_{ij} V_i \geq \beta_j \}$

Generator representation

$[\mathbf{P}, \mathbf{R}]$ where

- $\mathbf{P} \in \mathbb{Q}^{n \times p}$ is a set of p **points**: $\vec{P}_1, \dots, \vec{P}_p$
- $\mathbf{R} \in \mathbb{Q}^{n \times r}$ is a set of r **rays**: $\vec{R}_1, \dots, \vec{R}_r$

$\gamma([\mathbf{P}, \mathbf{R}]) \stackrel{\text{def}}{=} \{ (\sum_{j=1}^p \alpha_j \vec{P}_j) + (\sum_{j=1}^r \beta_j \vec{R}_j) \mid \forall j, \alpha_j, \beta_j \geq 0: \sum_{j=1}^p \alpha_j = 1 \}$

Double description of polyhedra (cont.)

Generator representation examples:

$$\gamma([\mathbf{P}, \mathbf{R}]) \stackrel{\text{def}}{=} \{ (\sum_{j=1}^p \alpha_j \vec{P}_j) + (\sum_{j=1}^r \beta_j \vec{R}_j) \mid \forall j, \alpha_j, \beta_j \geq 0 : \sum_{j=1}^p \alpha_j = 1 \}$$

Duality in polyhedra

Duality: P^* is the dual of P , so that:

- the generators of P^* are the constraints of P
- the constraints of P^* are the generators of P
- $P^{**} = P$

Polyhedra representations

Minimal representations

- A constraint / generator system is **minimal** if no constraint / generator can be omitted without changing the concretization
- Minimal representations are **not unique**

Example: three different constraint representations for a point

(a)

(b)

(c)

- (a) $y + x \geq 0, y - x \geq 0, y \leq 0, y \geq -5$ (non minimal)
- (b) $y + x \geq 0, y - x \geq 0, y \leq 0$ (minimal)
- (c) $x \leq 0, x \geq 0, y \leq 0, y \geq 0$ (minimal)

Polyhedra representations (cont.)

- **No bound** on the size of representations (even minimal ones)
- No best abstraction α

Example: a disc has infinitely many polyhedral over-approximations, but no best one

Chernikova's algorithm

Algorithm by Chernikova (1968), improved by LeVerge (1992) to switch from a constraint system to an equivalent generator system

Motivation: most operators are easier on one representation

- By **duality**, we can use the same algorithm to switch from generators to constraints
- The minimal generator system can be **exponential** in the original constraint system (e.g., hypercube: $2n$ constraints, 2^n vertices)
- **Equality** constraints and **lines** (pairs of opposed rays) may be handled separately and more efficiently
- Chernikova's algorithm minimizes the representation on-the-fly (not presented here)

Algorithm: **incrementally** add constraints one by one

Start with:
$$\begin{cases} \mathbf{P}_0 = \{ (0, \dots, 0) \} & \text{(origin)} \\ \mathbf{R}_0 = \{ \vec{x}_i, -\vec{x}_i \mid 1 \leq i \leq n \} & \text{(axes)} \end{cases}$$

Chernikova's algorithm (cont.)

Update $[\mathbf{P}_{k-1}, \mathbf{R}_{k-1}]$ to $[\mathbf{P}_k, \mathbf{R}_k]$

by adding one constraint $\vec{M}_k \cdot \vec{V} \geq C_k \in \langle \mathbf{M}, \vec{C} \rangle$:

start with $\mathbf{P}_k = \mathbf{R}_k = \emptyset$,

- for any $\vec{P} \in \mathbf{P}_{k-1}$ s.t. $\vec{M}_k \cdot \vec{P} \geq C_k$, add \vec{P} to \mathbf{P}_k
- for any $\vec{R} \in \mathbf{R}_{k-1}$ s.t. $\vec{M}_k \cdot \vec{R} \geq 0$, add \vec{R} to \mathbf{R}_k
- for any $\vec{P}, \vec{Q} \in \mathbf{P}_{k-1}$ s.t. $\vec{M}_k \cdot \vec{P} > C_k$ and $\vec{M}_k \cdot \vec{Q} < C_k$, add to \mathbf{P}_k :

$$\vec{O} \stackrel{\text{def}}{=} \frac{C_k - \vec{M}_k \cdot \vec{Q}}{\vec{M}_k \cdot \vec{P} - \vec{M}_k \cdot \vec{Q}} \vec{P} - \frac{C_k - \vec{M}_k \cdot \vec{P}}{\vec{M}_k \cdot \vec{P} - \vec{M}_k \cdot \vec{Q}} \vec{Q}$$

Chernikova's algorithm (cont.)

- for any $\vec{R}, \vec{S} \in \mathbf{R}_{k-1}$ s.t. $\vec{M}_k \cdot \vec{R} > 0$ and $\vec{M}_k \cdot \vec{S} < 0$, add to

\mathbf{R}_k :

$$\vec{O} \stackrel{\text{def}}{=} (\vec{M}_k \cdot \vec{S})\vec{R} - (\vec{M}_k \cdot \vec{R})\vec{S}$$

- for any $\vec{P} \in \mathbf{P}_{k-1}, \vec{R} \in \mathbf{R}_{k-1}$ s.t. either $\vec{M}_k \cdot \vec{P} > C_k$ and $\vec{M}_k \cdot \vec{R} < 0$, or $\vec{M}_k \cdot \vec{P} < C_k$ and $\vec{M}_k \cdot \vec{R} > 0$, add to \mathbf{P}_k :

$$\vec{O} \stackrel{\text{def}}{=} \vec{P} + \frac{C_k - \vec{M}_k \cdot \vec{P}}{\vec{M}_k \cdot \vec{R}} \vec{R}$$

Chernikova's algorithm example

Example:

$$P_0 = \{(0,0)\}$$

$$R_0 = \{(1,0), (-1,0), (0,1), (0,-1)\}$$

Chernikova's algorithm example

Example:

$$Y \geq 1$$

$$P_0 = \{(0, 0)\}$$

$$P_1 = \{(0, 1)\}$$

$$R_0 = \{(1, 0), (-1, 0), (0, 1), (0, -1)\}$$

$$R_1 = \{(1, 0), (-1, 0), (0, 1)\}$$

Chernikova's algorithm example

Example:

$$Y \geq 1$$

$$X + Y \geq 3$$

$$\mathbf{P}_0 = \{(0, 0)\}$$

$$\mathbf{P}_1 = \{(0, 1)\}$$

$$\mathbf{P}_2 = \{(2, 1)\}$$

$$\mathbf{R}_0 = \{(1, 0), (-1, 0), (0, 1), (0, -1)\}$$

$$\mathbf{R}_1 = \{(1, 0), (-1, 0), (0, 1)\}$$

$$\mathbf{R}_2 = \{(1, 0), (-1, 1), (0, 1)\}$$

Chernikova's algorithm example

Example:

$$\begin{array}{ll}
 Y \geq 1 & \mathbf{P}_0 = \{(0, 0)\} \\
 X + Y \geq 3 & \mathbf{P}_1 = \{(0, 1)\} \\
 X - Y \leq 1 & \mathbf{P}_2 = \{(2, 1)\} \\
 & \mathbf{P}_3 = \{(2, 1), (1, 2)\} \\
 & \mathbf{R}_0 = \{(1, 0), (-1, 0), (0, 1), (0, -1)\} \\
 & \mathbf{R}_1 = \{(1, 0), (-1, 0), (0, 1)\} \\
 & \mathbf{R}_2 = \{(1, 0), (-1, 1), (0, 1)\} \\
 & \mathbf{R}_3 = \{(0, 1), (1, 1)\}
 \end{array}$$

Operators on polyhedra

Abstract operators:

Given $X^\sharp, Y^\sharp \neq \perp$, we define:

$$X^\sharp \subseteq^\sharp Y^\sharp \quad \stackrel{\text{def}}{\iff} \quad \begin{cases} \forall \vec{P} \in \mathbf{P}_{X^\sharp} : \mathbf{M}_{Y^\sharp} \times \vec{P} \geq \vec{C}_{Y^\sharp} \\ \forall \vec{R} \in \mathbf{R}_{X^\sharp} : \mathbf{M}_{Y^\sharp} \times \vec{R} \geq \vec{0} \end{cases}$$

$$X^\sharp =^\sharp Y^\sharp \quad \stackrel{\text{def}}{\iff} \quad X^\sharp \subseteq^\sharp Y^\sharp \quad \text{and} \quad Y^\sharp \subseteq^\sharp X^\sharp$$

$$X^\sharp \cap^\sharp Y^\sharp \quad \stackrel{\text{def}}{=} \quad \left\langle \left[\begin{array}{c} \mathbf{M}_{X^\sharp} \\ \mathbf{M}_{Y^\sharp} \end{array} \right], \left[\begin{array}{c} \vec{C}_{X^\sharp} \\ \vec{C}_{Y^\sharp} \end{array} \right] \right\rangle \quad (\text{join constraint sets})$$

$\subseteq^\sharp, =^\sharp$ and \cap^\sharp are **exact** (in $\mathcal{P}(\mathbb{V} \rightarrow \mathbb{R})$)

Operators on polyhedra (cont.)

Join: $X^\# \cup^\# Y^\# \stackrel{\text{def}}{=} [[P_{X^\#} P_{Y^\#}], [R_{X^\#} R_{Y^\#}]]$ (join generator sets)

Examples:

two polytopes

a point and a line

$\cup^\#$ is **optimal** (in $\mathcal{P}(\mathbb{V} \rightarrow \mathbb{R})$):

we get the **topological closure of the convex hull** of $\gamma(X^\#) \cup \gamma(Y^\#)$

Operators on polyhedra (cont.)

Affine tests:

$$S^\#[\sum_j \alpha_j V_j \geq \beta] X^\# \stackrel{\text{def}}{=} \left\langle \left[\begin{array}{c} \mathbf{M}_{X^\#} \\ \alpha_1 \cdots \alpha_n \end{array} \right], \left[\begin{array}{c} \vec{C}_{X^\#} \\ \beta \end{array} \right] \right\rangle$$

Non-deterministic assignment:

$$S^\# [V_j \leftarrow [-\infty, +\infty]] X^\# \stackrel{\text{def}}{=} [\mathbf{P}_{X^\#}, [\mathbf{R}_{X^\#} \vec{x}_j (-\vec{x}_j)]]$$

- these operators are **exact** (in $\mathcal{P}(V \rightarrow \mathbb{R})$)
- other tests can be abstracted as $S^\# [c?] X^\# \stackrel{\text{def}}{=} X^\#$
(sound but not optimal)

Operators on polyhedra (cont.)

Affine assignment:

$$S^\sharp \llbracket V_j \leftarrow \sum_i \alpha_i V_i + \beta \rrbracket X^\sharp \stackrel{\text{def}}{=}$$

if $\alpha_j = 0$, $(S^\sharp \llbracket \sum_i \alpha_i V_i = V_j - \beta? \rrbracket \circ S^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket) X^\sharp$

if $\alpha_j \neq 0$, $\langle \mathbf{M}, \vec{C} \rangle$ where V_j is replaced with $\frac{1}{\alpha_j}(V_j - \sum_{i \neq j} \alpha_i V_i - \beta)$

- similar to the assignment in the equality domain
- the assignment is exact (in $\mathcal{P}(\mathbb{V} \rightarrow \mathbb{R})$)
- assignments can also be defined on the generator system
- for non-affine assignments: $S^\sharp \llbracket V \leftarrow e \rrbracket \stackrel{\text{def}}{=} S^\sharp \llbracket V \leftarrow [-\infty, +\infty] \rrbracket$
(sound but not optimal)

Polyhedra widening

$\mathcal{E}^\#$ has strictly increasing infinite chains \implies we need a widening

Definition:

Take $X^\#$ and $Y^\#$ in minimal constraint-set form

$$X^\# \nabla Y^\# \stackrel{\text{def}}{=} \{c \in X^\# \mid Y^\# \subseteq^\# \{c\}\}$$

We suppress any unstable constraint $c \in X^\#$, i.e., $Y^\# \not\subseteq^\# \{c\}$

Example:

Polyhedra widening

$\mathcal{E}^\#$ has strictly increasing infinite chains \implies we need a widening

Definition:

Take $X^\#$ and $Y^\#$ in minimal constraint-set form

$$X^\# \nabla Y^\# \stackrel{\text{def}}{=} \begin{aligned} & \{c \in X^\# \mid Y^\# \subseteq^\# \{c\}\} \\ \cup & \{c \in Y^\# \mid \exists c' \in X^\#: X^\# =^\# (X^\# \setminus c') \cup \{c\}\} \end{aligned}$$

We suppress any unstable constraint $c \in X^\#$, i.e., $Y^\# \not\subseteq^\# \{c\}$

We also keep constraints $c \in Y^\#$ equivalent to those in $X^\#$, i.e., when $\exists c' \in X^\#: X^\# =^\# (X^\# \setminus c') \cup \{c\}$

Example:

Example analysis

Example

```

X ← 2; I ← 0;
while I < 10 do
  if rand(0, 1) = 0 then X ← X + 2 else X ← X - 3;
  I ← I + 1

```

Loop invariant:

increasing iterations with widening:

$$\begin{aligned}
 X_1^\sharp &= \{X = 2, I = 0\} \\
 X_2^\sharp &= \{X = 2, I = 0\} \nabla (\{X = 2, I = 0\} \cup^\sharp \{X \in [-1, 4], I = 1\}) \\
 &= \{X = 2, I = 0\} \nabla \{I \in [0, 1], 2 - 3I \leq X \leq 2I + 2\} \\
 &= \{I \geq 0, 2 - 3I \leq X \leq 2I + 2\}
 \end{aligned}$$

decreasing iteration: (recover $I \leq 10$)

$$\begin{aligned}
 X_3^\sharp &= \{X = 2, I = 0\} \cup^\sharp \{I \in [1, 10], 2 - 3I \leq X \leq 2I + 2\} \\
 &= \{I \in [0, 10], 2 - 3I \leq X \leq 2I + 2\}
 \end{aligned}$$

at the loop exit, we find eventually: $I = 10 \wedge X \in [-28, 22]$

Partial conclusion

Cost vs. precision:

Domain	Invariants	Memory cost	Time cost (per op.)
intervals	$V \in [\ell, h]$	$\mathcal{O}(V)$	$\mathcal{O}(V)$
affine equalities	$\sum_i \alpha_i V_i = \beta_i$	$\mathcal{O}(V ^2)$	$\mathcal{O}(V ^3)$
polyhedra	$\sum_i \alpha_i V_i \geq \beta_i$	unbounded, exponential in practice	

- domains provide a tradeoff between precision and cost
- relational invariants are sometimes necessary**
even to prove non-relational properties
- an abstract domain is defined by
 - a choice of **abstract properties** and **operators** (semantic aspect)
 - data-structures** and **algorithms** (algorithmic aspect)
- an abstract domain mixes two kinds of approximations:
 - static** approximations (choice of abstract properties)
 - dynamic** approximations (widening)

Weakly relational domains

Principle: restrict the expressiveness of polyhedra to be more efficient at the cost of precision

Example domains:

- **Based on constraint propagation:** (closure algorithms)
 - Octagons: $\pm X \pm Y \leq c$
shortest path closure: $x + y \leq c \wedge -y + z \leq d \implies x + z \leq c + d$
quadratic memory cost, cubic time cost
 - Two-variables per inequality: $\alpha x + \beta y \leq c$
slightly more complex closure algorithm, by Nelson
 - Octahedra: $\sum \alpha_i V_i \leq c, \alpha_i \in \{-1, 0, 1\}$
incomplete propagation, to avoid exponential cost
 - Pentagons: $X - Y \leq 0$
restriction of octagons
incomplete propagation, aims at linear cost
- **Based on linear programming:**
 - Template polyhedra: $\mathbf{M} \times \vec{V} \geq \vec{C}$ for a fixed \mathbf{M}

Integers

Issue:

in relational domains we used implicitly **real-valued** environments $\mathbb{V} \rightarrow \mathbb{R}$
 our concrete semantics is based on **integer-valued** environments $\mathbb{V} \rightarrow \mathbb{Z}$

In fact, an abstract element $X^\#$ does not represent $\gamma(X^\#) \subseteq \mathbb{R}^{|\mathbb{V}|}$, but:

$$\gamma_{\mathbb{Z}}(X^\#) \stackrel{\text{def}}{=} \gamma(X^\#) \cap \mathbb{Z}^{|\mathbb{V}|} \quad (\text{keep only integer points})$$

Soundness and exactness for $\gamma_{\mathbb{Z}}$

- $\subseteq^\#$ and $=^\#$ are no longer exact
 e.g., $\gamma(2X = 1) \neq \gamma(\perp)$, but $\gamma_{\mathbb{Z}}(2X = 1) = \gamma(\perp) = \emptyset$
- $\cap^\#$ and affine tests are still exact
- affine and non-deterministic assignments are no longer exact
 e.g., $R^\# = (Y = 2X)$, $S^\# \llbracket X \leftarrow [-\infty, +\infty] \rrbracket R^\# = \top$,
 but $S \llbracket X \leftarrow [-\infty, +\infty] \rrbracket (\gamma_{\mathbb{Z}}(R^\#)) = \mathbb{Z} \times (2\mathbb{Z})$
- all the operators are **still sound**
 $\mathbb{Z}^{|\mathbb{V}|} \subseteq \mathbb{R}^{|\mathbb{V}|}$, so $\forall X^\# : \gamma_{\mathbb{Z}}(X^\#) \subseteq \gamma(X^\#)$

(in general, soundness, exactness, optimality depend on the definition of γ)

Integers (cont.)

Possible solutions:

- **enrich** the domain (add exact representations for operation results)
 - congruence equalities: $\wedge_i \sum_j \alpha_{ij} V_j \equiv \beta_i [\gamma_i]$ (Granger 1991)
 - Pressburger arithmetic (first order logic with 0, 1, +)
decidable, but with **very costly** algorithms

- design **optimal** (non-exact) operators

also based on **costly algorithms**, e.g.:

- normalization: integer hull
smallest polyhedra containing $\gamma_Z(X^\sharp)$
- emptiness testing: integer programming
NP-hard, while linear programming is P

- **pragmatic** solution (efficient, non-optimal)

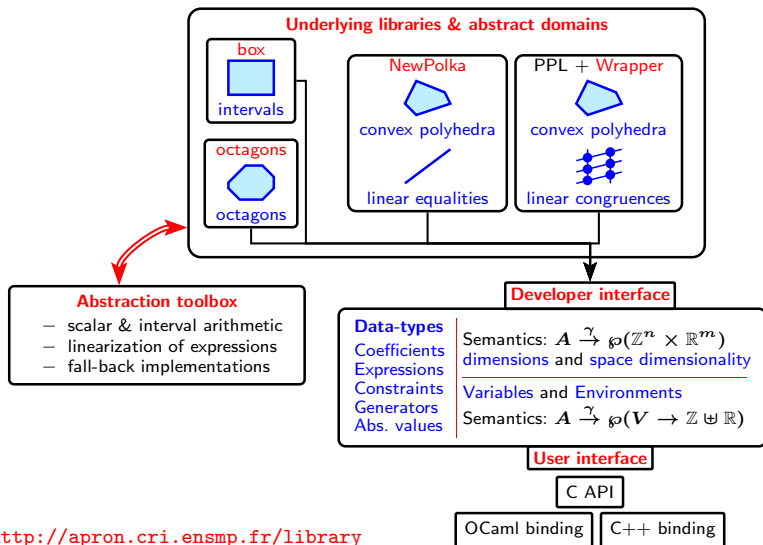

use regular operators for $\mathbb{R}^{|\mathbb{V}|}$, then tighten each constraint to remove as many non-integer points as possible

e.g.: $2X + 6Y \geq 3 \rightarrow X + 3Y \geq 2$

Note: **we abstract integers as reals!**

Using the Apron Library

Apron library

<http://apron.cri.ensmp.fr/library>

Apron modules

The Apron module contains sub-modules:

- **Abstract1**
abstract elements
- **Manager**
abstract domains (arguments to all Abstract1 operations)
- **Polka**
creates a manager for polyhedra abstract elements
- **Var**
integer or real program variables (denoted as a string)
- **Environment**
sets of integer and real program variables
- **Texpr1**
arithmetic expression trees
- **Tcons1**
arithmetic constraints (based on Texpr1)
- **Coeff**
numeric coefficients (appear in Texpr1, Tcons1)

Variables and environments

Variables: type `Var.t`

variables are denoted by their name, as a string:

(assumes implicitly that no two program variables have the same name)

- `Var.of_string: string -> Var.t`

Environments: type `Environment.t`

an abstract element abstracts a set of mappings in $\mathbb{V} \rightarrow \mathbb{R}$

\mathbb{V} is the environment; it contains integer-valued and real-valued variables

- `Environment.make: Var.t array -> Var.t array -> t`
`make ivars rvars` creates an environment with `ivars` integer variables and `rvars` real variables;
`make [] []` is the empty environment
- `Environment.add: Environment.t -> Var.t array -> Var.t array -> t`
`add env ivars rvars` adds some integer or real variables to `env`
- `Environment.remove: t -> Var.t array -> t`

internally, an abstract element abstracts a set of points in \mathbb{R}^n ;

the environment maintains the mapping from variable names to dimensions in $[1, n]$

Expressions

Concrete expression trees: type `Texpr1.expr`

```

type expr = | Cst of Coeff.t                                (constants)
            | Var of Var.t                                  (variables)
            | Unop of unop * expr * typ * round         (unary op.)
            | Binop of binop * expr * expr * typ * round (binary op.)
  
```

- unary operators

```
type Texpr1.unop = Neg | ...
```

- binary operators

```
type Texpr1.binop = Add | Sub | Mul | Div | ...
```

- numeric type:

(we only use integers, but reals and floats are also possible)

```
type Texpr1.typ = Int | ...
```

- rounding direction:

(only useful for the division on integers; we use rounding to zero, i.e., truncation)

```
type Texpr1.round = Zero | ...
```

Expressions (cont.)

Internal expression form: type `Texpr1.t`

concrete expression trees must be converted to an internal form to be used in abstract operations

- `Texpr1.of_expr`: `Environment.t -> Texpr1.expr -> Texpr1.t`
(the environment is used to convert variable names to dimensions in \mathbb{R}^n)

Coefficients: type `Coeff.t`

can be either a **scalar** `{c}` or an **interval** `[a, b]`

we can use the `Mpqf` module to convert from strings to arbitrary precision integers, before converting them into `Coeff.t`:

- for scalars `{c}`:
`Coeff.s_of_mpqf (Mpqf.of_string c)`
- for intervals `[a, b]`:
`Coeff.i_of_mpqf (Mpqf.of_string a) (Mpqf.of_string b)`

Constraints

Constraints: type `Tcons1.t`

constructor `expr` \bowtie 0:

- `Tcons1.make`: `Texpr1.t -> TCons1.typ -> Tcons1.t`

where:

<code>type Tcons1.typ =</code>	<code>SUPEQ</code>		<code>SUP</code>		<code>EQ</code>		<code>DISEQ</code>		<code>...</code>
	\geq		$>$		$=$		\neq		

Note: avoid using `DISEQ` directly, which is not very precise;
but use a disjunction of two `SUP` constraints instead

Constraint arrays: type `Tcons1.earray`

abstract operators do not use constraints, but constraint arrays instead

Example: constructing an array `ar` containing a single constraint:

```
let c = Tcons1.make texpr1 typ in
let ar = Tcons1.array_make env 1 in
Tcons1.array_set ar 0 c
```

Abstract operators

Abstract elements: type `Abstract1.t`

- `Abstract1.top`: `Manager.t -> Environment.t -> t`
create an abstract element where variables have any value
- `Abstract1.env`: `t -> Environment.t`
recover the environment on which the abstract element is defined
- `Abstract1.change_environment`: `Manager.t -> t -> Environment.t -> bool -> t`
set the new environment, adding or removing variables if necessary
the `bool` argument should be set to `false`: variables are not initialized
- `Abstract1.assign_texpr`: `Manager.t -> t -> Var.t -> Texpr1.t -> t option -> t`
abstract assignment; the `option` argument should be set to `None`
- `Abstract1.forget_array`: `Manager.t -> t -> Var.t array -> bool -> t`
non-deterministic assignment: forget the value of variables (when `bool` is `false`)
- `Abstract1.meet_tcons_array`: `Manager.t -> t -> Tcons1.earray -> t`
abstract test: add one or several constraint(s)

Abstract operators (cont.)

- `Abstract1.join`: `Manager.t -> t -> t -> t`
abstract union \cup^\sharp
- `Abstract1.meet`: `Manager.t -> t -> t -> t`
abstract intersection \cap^\sharp
- `Abstract1.widen`: `Manager.t -> t -> t -> t`
widening ∇
- `Abstract1.is_leq`: `Manager.t -> t -> t -> bool`
 \subseteq^\sharp : return true if the first argument is included in the second
- `Abstract1.is_bottom`: `Manager.t -> t -> t bool`
whether the abstract element represents \emptyset
- `Abstract1.print`: `Format.formatter -> t -> unit`
print the abstract element

Contract:

- operators return a new, immutable abstract element (functional style)
- operators return over-approximations
(not always optimal; e.g.: for non-linear expressions)
- predicates return `true` (definitely true) or `false` (don't know)

Managers

Managers: type `Manager.t`

The manager denotes a choice of abstract domain

To use the polyhedra domain, construct the manager with:

- `let manager = Polka.manager_alloc_loose ()`

the same `manager` variable is passed to all `Abstract1` function

to choose another domain, you only need to change the line defining `manager`

Other libraries:

- `Polka.manager_alloc_equalities` (affine equalities)
- `Polka.manager_alloc_strict` (\geq and $>$ affine inequalities over \mathbb{R})
- `Box.manager_alloc` (intervals)
- `Oct.manager_alloc` (octagons)
- `Ppl.manager_alloc_grid` (affine congruences)
- `PolkaGrid.manager_alloc` (affine inequalities and congruences)

Errors

Argument compatibility: ensure that:

- the **same manager** is used when creating and using an abstract element
the type system checks for the compatibility between `'a Manager.t` and `'a Abstract1.t`
- expressions and abstract elements have the **same environment**
- assigned **variables exist** in the environment of the abstract element
- both abstract elements of binary operators (\cup , \cap , ∇ , \subseteq) are defined on the **same environment**

Failure to ensure this results in a **Manager.Error** exception

Abstract domain skeleton using Apron

```

open Apron

module RelationalDomain = (struct
  (* manager *)
  type man = Polka.loose Polka.t
  let manager = Polka.manager_alloc_loose ()

  (* abstract elements *)
  type t = man Abstract1.t

  (* utilities *)
  val expr_to_texpr:  expr -> Texpr1.expr

  (* implementation *)
  ...
end: ENVIRONMENT_DOMAIN)

```

To compile: add to the Makefile:

```

OCAMLINC = ... -I +zarith -I +apron -I +gmp
CMA = bigarray.cma gmp.cma apron.cma polkaMPQ.cma

```

Fall-back assignments and tests

```

let rec expr_to_texpr = function
| AST_binary (op, e1, e2) ->
  match op with
  | AST_PLUS -> Texpr1.Binop ...
  | ...
  | _ -> raise Top

let assign env var expr =
  try
    let e = expr_to_texpr expr in
    Abstract1.assign_texpr ...
  with Top -> Abstract1.forget_array ...

let compare abs e1 e2 =
  try
    ...
    Abstract1.meet_tcons_array ...
  with Top -> abs

```

Idea:

raise `Top` to abort a computation

catch it to fall-back to sound coarse assignments and tests
