## Operational semantics

### Mathematical description of the executions of a program

- 1 A **model** of programs: **transition systems**
  - ▶ definition, a **small step semantics**
  - ▶ a few common examples
- 2 **Trace semantics**: a kind of **big step** semantics
  - ▶ **finite** and **infinite** executions
  - ▶ **fixpoint**-based definitions
  - ▶ notion of **compositional semantics**

# Outline

- 1 Transition systems and small step semantics
  - Definition and properties
  - Examples
- 2 Traces semantics
- 3 Summary

# Definition

We will characterize a program by:

- **states:**  
photography of the program status at an instant of the execution
- **execution steps:** how do we move from one state to the next one

## Definition: transition systems (TS)

A **transition system** is a tuple  $(\mathcal{S}, \rightarrow)$  where:

- $\mathcal{S}$  is the **set of states** of the system
- $\rightarrow \subseteq \mathcal{P}(\mathcal{S} \times \mathcal{S})$  is the **transition relation** of the system

## Note:

- the set of states **may be infinite**

## Transition systems: properties of the transition relation

A **deterministic** system is such that a state fully determines the next state

$$\forall s_0, s_1, s'_1 \in \mathbb{S}, (s_0 \rightarrow s_1 \wedge s_0 \rightarrow s'_1) \implies s_1 = s'_1$$

Otherwise, a transition system is **non deterministic**, i.e.:

$$\exists s_0, s_1, s'_1 \in \mathbb{S}, s_0 \rightarrow s_1 \wedge s_0 \rightarrow s'_1 \wedge s_1 \neq s'_1$$

### Notes:

- the transition relation  $\rightarrow$  defines atomic execution steps; it is often called **small-step semantics** or **structured operational semantics**
- steps are **discrete** (not continuous)  
to describe both discrete and continuous behaviors, we would need to look at *hybrid systems* (beyond the scope of this lecture)

# Transition systems: initial and final states

## Initial / final states:

we often consider transition systems with a set of initial and final states:

- a set of **initial states**  $\mathbb{S}_I \subseteq \mathbb{S}$  denotes states where the execution should start
- a set of **final states**  $\mathbb{S}_F \subseteq \mathbb{S}$  denotes states where the execution should reach the end of the program

When needed, we add these to the definition of the transition systems  $((\mathbb{S}, \rightarrow, \mathbb{S}_I, \mathbb{S}_F)$ .

## Blocking state (not the same as final state):

- a state  $s_0 \in \mathbb{S}$  is **blocking** when it is the origin of no transition:  
 $\forall s_1 \in \mathbb{S}, \neg(s_0 \rightarrow s_1)$
- example: we often introduce an **error state** (usually noted  $\Omega$  to denote the erroneous, blocking configuration)

# Outline

- 1 Transition systems and small step semantics
  - Definition and properties
  - Examples
- 2 Traces semantics
- 3 Summary

# Finite automata as transition systems

We can clearly formalize the **word recognition** by a finite automaton using a transition system:

- We consider **automaton**  $\mathcal{A} = (Q, q_i, q_f, \rightarrow)$
- A “**state**” is defined by:
  - ▶ the **remaining of the word to recognize**
  - ▶ the **automaton state** that has been reached so far
 thus,  $\mathbb{S} = Q \times L^*$
- The **transition relation**  $\rightarrow$  of the transition system is defined by:

$$(q_0, aw) \rightarrow (q_1, w) \iff q_0 \xrightarrow{a} q_1$$

- The **initial** and **final states** are defined by:

$$\mathbb{S}_{\mathcal{I}} = \{(q_i, w) \mid w \in L^*\} \qquad \mathbb{S}_{\mathcal{F}} = \{(q_f, \epsilon)\}$$

# Pure $\lambda$ -calculus

A **bare bones model of functional programming**:

## $\lambda$ -terms

The set of  $\lambda$ -terms is defined by:

$t, u, \dots$	$::=$	$x$	variable
		$\lambda x \cdot t$	abstraction
		$t u$	application

## $\beta$ -reduction

- $(\lambda x \cdot t) u \rightarrow_{\beta} t[x \leftarrow u]$
- if  $u \rightarrow_{\beta} v$  then  $\lambda x \cdot u \rightarrow_{\beta} \lambda x \cdot v$
- if  $u \rightarrow_{\beta} v$  then  $u t \rightarrow_{\beta} v t$
- if  $u \rightarrow_{\beta} v$  then  $t u \rightarrow_{\beta} t v$

The  $\lambda$ -calculus defines a transition system:

- $\mathbb{S}$  is the set of  $\lambda$ -terms and  $\rightarrow_{\beta}$  the transition relation
- $\rightarrow_{\beta}$  is **non-deterministic**; example ?  
though, ML fixes an execution order
- given a lambda term  $t_0$ , we may consider  $(\mathbb{S}, \rightarrow_{\beta}, \mathbb{S}_{\mathcal{I}})$  where  $\mathbb{S}_{\mathcal{I}} = \{t_0\}$
- **blocking states** are terms with no redex  $(\lambda x \cdot u) v$

# A MIPS like assembly language: syntax

We now consider a (very simplified) **assembly language**

- machine integers: sequences of 32-bits (set:  $\mathbb{B}^{32}$ )
- instructions are encoded over 32-bits (set:  $\mathbb{I}_{\text{MIPS}}$ )  
and stored into the same space as data (i.e.,  $\mathbb{I}_{\text{MIPS}} \subseteq \mathbb{B}^{32}$ )
- we assume a fixed set of addresses  $\mathbb{A}$

## Memory configurations

- **Program counter pc**  
current instruction
- **General purpose registers**  
 $r_0 \dots r_{31}$
- **Main memory (RAM)**  
 $\text{mem} : \mathbb{A} \rightarrow \mathbb{B}^{32}$   
where  $\mathbb{A} \subseteq \mathbb{B}^{32}$

## Instructions

$i ::= (\in \mathbb{I}_{\text{MIPS}})$   
 | **add**  $r_d, r_s, r_{s'}$     addition  
 | **addi**  $r_d, r_s, v$     add.  $v \in \mathbb{B}^{32}$   
 | **sub**  $r_d, r_s, r_{s'}$     subtraction  
 | **b t**    branch  
 | **blt**  $r_s, r_{s'}, t$     cond. branch  
 | **ld**  $r_d, o, r_x$     relative load  
 | **st**  $r_d, o, r_x$     relative store  
 $v, t, o \in \mathbb{B}^{32}, d, s, s', x \in [0, 31]$

# A MIPS like assembly language: states

## Definition: state

A state is a tuple  $(\pi, \rho, \mu)$  which comprises:

- A **program counter** value  $\pi \in \mathbb{B}^{32}$
- A function mapping each **general purpose register** to its value  $\rho : \{0, \dots, 31\} \rightarrow \mathbb{B}^{32}$
- A function mapping each **memory cell** to its value  $\mu : \mathbb{A} \rightarrow \mathbb{B}^{32}$

What would a **dangerous state** be ?

- writing **over an instruction**
- reading or writing **outside the program's memory**
- we cannot fully formalize these yet...  
as we need to formalize the behavior of each instruction first

# A MIPS like assembly language: transition relation

We assume a state  $s = (\pi, \rho, \mu)$  and that  $\mu(\pi) = i$ ; then:

- if  $i = \text{add } r_d, r_s, r_{s'}$ , then:

$$s \rightarrow (\pi + 4, \rho[d \leftarrow \rho(s) + \rho(s')], \mu)$$

- if  $i = \text{addi } r_d, r_s, v$ , then:

$$s \rightarrow (\pi + 4, \rho[d \leftarrow \rho(s) + v], \mu)$$

- if  $i = \text{sub } r_d, r_s, r_{s'}$ , then:

$$s \rightarrow (\pi + 4, \rho[d \leftarrow \rho(s) - \rho(s')], \mu)$$

- if  $i = \text{b } t$ , then:

$$s \rightarrow (t, \rho, \mu)$$

# A MIPS like assembly language: transition relation

We assume a state  $s = (\pi, \rho, \mu)$  and that  $\mu(\pi) = i$ ; then:

- if  $i = \text{blt } r_s, r_{s'}, t$ , then:

$$s \rightarrow \begin{cases} (t, \rho, \mu) & \text{if } \rho(s) < \rho(s') \\ (\pi + 4, \rho, \mu) & \text{otherwise} \end{cases}$$

- if  $i = \text{ld } r_d, o, r_x$ , then:

$$s \rightarrow \begin{cases} (\pi + 4, \rho[d \leftarrow \mu(\rho(x) + o)], \mu) & \text{if } \rho(x) + o \in \mathbb{A} \\ \Omega & \text{otherwise} \end{cases}$$

- if  $i = \text{st } r_d, o, r_x$ , then:

$$s \rightarrow \begin{cases} (\pi + 4, \rho, \mu[\rho(x) + o \leftarrow \rho(d)]) & \text{if } \rho(x) + o \in \mathbb{A} \\ \Omega & \text{otherwise} \end{cases}$$

# A simple imperative language: syntax

We now look at a more classical **imperative language** (intuitively, a bare-bone subset of C):

- **variables**  $\mathbb{X}$ : finite, predefined set of variables
- **labels**  $\mathbb{L}$ : before and after each statement
- **values**  $\mathbb{V}$ :  $\mathbb{V}_{\text{int}} \cup \mathbb{V}_{\text{float}} \cup \dots$

## Syntax

$e$	$::= v \ (v \in \mathbb{V}) \mid x \ (x \in \mathbb{X}) \mid e + e \mid e * e \mid \dots$	expressions
$c$	$::= \text{TRUE} \mid \text{FALSE} \mid e < e \mid e = e$	conditions
$i$	$::= x := e;$	assignment
	$\mid \text{if}(c) \ b \ \text{else} \ b$	condition
	$\mid \text{while}(c) \ b$	loop
$b$	$::= \{i; \dots; i;\}$	block, program( $\mathbb{P}$ )

## A simple imperative language: states

A **non-error state** should fully describe the configuration at one instant of the program execution

The **control state** defines *where* the program currently is

- analogous to the **program counter**
- can be defined by adding **labels**  $\mathbb{L} = \{\ell_0, \ell_1, \dots\}$  between each pair of consecutive statements; then:

$$\mathbb{S} = \mathbb{L} \times \mathbb{M} \uplus \{\Omega\}$$

- or by the **program remaining to be executed**; then:

$$\mathbb{S} = \mathbb{P} \times \mathbb{M} \uplus \{\Omega\}$$

The **memory state** defines the current contents of the memory

$$m \in \mathbb{M} = \mathbb{X} \longrightarrow \mathbb{V}$$

# A simple imperative language: semantics of expressions

- The **semantics**  $\llbracket e \rrbracket$  of expression  $e$  should evaluate each expression into a value, given a memory state
- **Evaluation errors** may occur: division by zero... error value is also noted  $\Omega$

Thus:  $\llbracket e \rrbracket : \mathbb{M} \longrightarrow \mathbb{V} \uplus \{\Omega\}$

**Definition**, by **induction over the syntax**:

$$\begin{aligned} \llbracket v \rrbracket(m) &= v \\ \llbracket x \rrbracket(m) &= m(x) \\ \llbracket e_0 + e_1 \rrbracket(m) &= \llbracket e_0 \rrbracket(m) \pm \llbracket e_1 \rrbracket(m) \\ \llbracket e_0 / e_1 \rrbracket(m) &= \begin{cases} \Omega & \text{if } \llbracket e_1 \rrbracket(m) = 0 \\ \llbracket e_0 \rrbracket(m) / \llbracket e_1 \rrbracket(m) & \text{otherwise} \end{cases} \end{aligned}$$

where  $\underline{\oplus}$  is the machine implementation of operator  $\oplus$ , and is  $\Omega$ -strict, i.e.,  $\forall v \in \mathbb{V}, v \underline{\oplus} \Omega = \Omega \underline{\oplus} v = \Omega$ .

# A simple imperative language: semantics of conditions

- The **semantics**  $\llbracket c \rrbracket$  of **condition**  $c$  should return a *boolean value*
- It follows a similar definition to that of the semantics of expressions:

$$\llbracket c \rrbracket : \mathbb{M} \longrightarrow \mathbb{V}_{\text{bool}} \uplus \{\Omega\}$$

**Definition**, by **induction over the syntax**:

$$\begin{aligned} \llbracket \text{TRUE} \rrbracket(m) &= \text{TRUE} \\ \llbracket \text{FALSE} \rrbracket(m) &= \text{FALSE} \\ \llbracket e_0 < e_1 \rrbracket(m) &= \begin{cases} \text{TRUE} & \text{if } \llbracket e_0 \rrbracket(m) < \llbracket e_1 \rrbracket(m) \\ \text{FALSE} & \text{if } \llbracket e_0 \rrbracket(m) \geq \llbracket e_1 \rrbracket(m) \\ \Omega & \text{if } \llbracket e_0 \rrbracket(m) = \Omega \text{ or } \llbracket e_1 \rrbracket(m) = \Omega \end{cases} \\ \llbracket e_0 = e_1 \rrbracket(m) &= \begin{cases} \text{TRUE} & \text{if } \llbracket e_0 \rrbracket(m) = \llbracket e_1 \rrbracket(m) \\ \text{FALSE} & \text{if } \llbracket e_0 \rrbracket(m) \neq \llbracket e_1 \rrbracket(m) \\ \Omega & \text{if } \llbracket e_0 \rrbracket(m) = \Omega \text{ or } \llbracket e_1 \rrbracket(m) = \Omega \end{cases} \end{aligned}$$

# A simple imperative language: transitions

**Transitions** describe **local program execution steps**, thus are defined by case analysis on the program statements

Case of **assignment**  $l_0 : x = e; l_1$

- if  $\llbracket e \rrbracket(m) \neq \Omega$ , then  $(l_0, m) \rightarrow (l_1, m[x \leftarrow \llbracket e \rrbracket(m)])$
- if  $\llbracket e \rrbracket(m) = \Omega$ , then  $(l_0, m) \rightarrow \Omega$

Case of **condition**  $l_0 : \text{if}(c)\{l_1 : b_t l_2\} \text{ else}\{l_3 : b_f l_4\} l_5$

- if  $\llbracket c \rrbracket(m) = \text{TRUE}$ , then  $(l_0, m) \rightarrow (l_1, m)$
- if  $\llbracket c \rrbracket(m) = \text{FALSE}$ , then  $(l_0, m) \rightarrow (l_3, m)$
- if  $\llbracket c \rrbracket(m) = \Omega$ , then  $(l_0, m) \rightarrow \Omega$
- $(l_2, m) \rightarrow (l_5, m)$
- $(l_4, m) \rightarrow (l_5, m)$

# A simple imperative language: transitions

Case of **loop**  $l_0 : \text{while}(c)\{l_1 : b_t l_2\} l_3$

- if  $\llbracket c \rrbracket(m) = \text{TRUE}$ , then  $\begin{cases} (l_0, m) \rightarrow (l_1, m) \\ (l_2, m) \rightarrow (l_1, m) \end{cases}$
- if  $\llbracket c \rrbracket(m) = \text{FALSE}$ , then  $\begin{cases} (l_0, m) \rightarrow (l_3, m) \\ (l_2, m) \rightarrow (l_3, m) \end{cases}$
- if  $\llbracket c \rrbracket(m) = \Omega$ , then  $\begin{cases} (l_0, m) \rightarrow \Omega \\ (l_2, m) \rightarrow \Omega \end{cases}$

Case of  $\{l_0 : i_0; l_1 : \dots; l_{n-1} i_{n-1}; l_n\}$

- the transition relation is defined by the individual instructions

# Extending the language with non-determinism

The language we have considered so far is a bit **limited**:

- it is **deterministic**: at most one transition possible from any state
- it does not support the **input of values**

Changes if we model non deterministic inputs...

... with an input instruction:

- $i ::= \dots \mid x := \mathbf{input}()$
- $\ell_0 : x := \mathbf{input}(); \ell_1$  generates transitions
 
$$\forall v \in \mathbb{V}, (\ell_0, m) \rightarrow (\ell_1, m[x \leftarrow v])$$
- one instruction induces non determinism

... with a random function:

- $e ::= \dots \mid \mathbf{rand}()$
- **expressions** have a **non-deterministic** semantics:
 
$$\llbracket e \rrbracket : \mathbb{M} \rightarrow \mathcal{P}(\mathbb{V} \uplus \{\Omega\})$$

$$\llbracket \mathbf{rand}() \rrbracket (m) = \mathbb{V}$$

$$\llbracket v \rrbracket (m) = \{v\}$$

$$\llbracket c \rrbracket : \mathbb{M} \rightarrow \mathcal{P}(\mathbb{V}_{\text{bool}} \uplus \{\Omega\})$$
- all instructions induce non determinism

# Semantics of real world programming languages

## C language:

- several **norms**: ANSI C'99, ANSI C'11, K&R...
- not fully specified:
  - ▶ **undefined behavior**
  - ▶ **implementation dependent behavior**: architecture (ABI) or implementation (compiler...)
  - ▶ unspecified parts: leave room for implementation of compilers and optimizations
- **formalizations** in HOL (C'99), in Coq (CompCert C compiler)

## OCaml language:

- more formal...
- ... but still with some unspecified parts, e.g., execution order

# Outline

1 Transition systems and small step semantics

2 Traces semantics

- Definitions
- Finite traces semantics
- Fixpoint definition
- Compositionality
- Infinite traces semantics

3 Summary

# Execution traces

- So far, we considered only states and atomic transitions
- We now consider program **executions** as a whole

## Definition: traces

- A **finite trace** is a finite sequence of states  $s_0, \dots, s_n$ , noted  $\langle s_0, \dots, s_n \rangle$
- An **infinite trace** is an infinite sequence of states  $\langle s_0, \dots \rangle$

Besides, we write:

- $\mathbb{S}^*$  for the **set of finite traces**
- $\mathbb{S}^\omega$  for the **set of infinite traces**
- $\mathbb{S}^\infty = \mathbb{S}^* \cup \mathbb{S}^\omega$  for the **set of finite or infinite traces**

# Operations on traces: concatenation

## Definition: concatenation

The **concatenation operator**  $\cdot$  is defined by:

$$\begin{aligned} \langle s_0, \dots, s_n \rangle \cdot \langle s'_0, \dots, s'_{n'} \rangle &= \langle s_0, \dots, s_n, s'_0, \dots, s'_{n'} \rangle \\ \langle s_0, \dots, s_n \rangle \cdot \langle s'_0, \dots \rangle &= \langle s_0, \dots, s_n, s'_0, \dots \rangle \\ \langle s_0, \dots, s_n, \dots \rangle \cdot \sigma' &= \langle s_0, \dots, s_n, \dots \rangle \end{aligned}$$

We also define:

- the **empty trace**  $\epsilon$ , neutral element for  $\cdot$
- the **length** operator  $|\cdot|$ :

$$\begin{cases} |\epsilon| &= 0 \\ |\langle s_0, \dots, s_n \rangle| &= n + 1 \\ |\langle s_0, \dots \rangle| &= \omega \end{cases}$$

# Comparing traces: the prefix order relation

## Definition: prefix order relation

Relation  $\prec$  is defined by:

$$\langle s_0, \dots, s_n \rangle \prec \langle s'_0, \dots, s'_{n'} \rangle \iff \begin{cases} n \leq n' \\ \forall i \in \llbracket 0, n \rrbracket, s_i = s'_i \end{cases}$$

$$\langle s_0, \dots \rangle \prec \langle s'_0, \dots \rangle \iff \forall i \in \mathbb{N}, s_i = s'_i$$

$$\langle s_0, \dots, s_n \rangle \prec \langle s'_0, \dots \rangle \iff \forall i \in \llbracket 0, n \rrbracket, s_i = s'_i$$

**Proof:** straightforward application of the definition of order relations

# Outline

1 Transition systems and small step semantics

2 Traces semantics

- Definitions
- Finite traces semantics
- Fixpoint definition
- Compositionality
- Infinite traces semantics

3 Summary

# Semantics of finite traces

We consider a transition system  $\mathcal{S} = (\mathbb{S}, \rightarrow)$

## Definition

The **finite traces semantics**  $\llbracket \mathcal{S} \rrbracket^*$  is defined by:

$$\llbracket \mathcal{S} \rrbracket^* = \{ \langle s_0, \dots, s_n \rangle \in \mathbb{S}^* \mid \forall i, s_i \rightarrow s_{i+1} \}$$

## Example:

- contrived transition system  $\mathcal{S} = (\{a, b, c, d\}, \{(a, b), (b, a), (b, c)\})$
- finite traces semantics:

$$\llbracket \mathcal{S} \rrbracket^* = \left\{ \begin{array}{ll} \epsilon, & \\ \langle a, b, \dots, a, b, a \rangle, & \langle b, a, \dots, a, b, a \rangle, \\ \langle a, b, \dots, a, b, a, b \rangle, & \langle b, a, \dots, a, b, a, b \rangle, \\ \langle a, b, \dots, a, b, a, b, c \rangle, & \langle b, a, \dots, a, b, a, b, c \rangle \\ \langle c \rangle, & \langle d \rangle \end{array} \right\}$$

# Interesting subsets of the finite trace semantics

We consider a transition system  $\mathcal{S} = (\mathbb{S}, \rightarrow, \mathbb{S}_I, \mathbb{S}_F)$

- the **initial traces**, i.e., starting from an initial state:

$$\{\langle s_0, \dots, s_n \rangle \in \llbracket \mathcal{S} \rrbracket^* \mid s_0 \in \mathbb{S}_I\}$$

- the **traces reaching a blocking state**:

$$\{\sigma \in \llbracket \mathcal{S} \rrbracket^* \mid \forall \sigma' \in \llbracket \mathcal{S} \rrbracket^*, \sigma \prec \sigma' \implies \sigma = \sigma'\}$$

- the **traces ending in a final state**:

$$\{\langle s_0, \dots, s_n \rangle \in \llbracket \mathcal{S} \rrbracket^* \mid s_n \in \mathbb{S}_F\}$$

- the **maximal traces** are both initial and final

**Example** (same transition system, with  $\mathbb{S}_I = \{a\}$  and  $\mathbb{S}_F = \{c\}$ ):

- traces from an initial state ending in a final state:

$$\{\langle a, b, \dots, a, b, a, b, c \rangle\}$$

# Example: finite automaton

We consider the **example of the previous course**:

$$L = \{a, b\} \quad Q = \{q_0, q_1, q_2\}$$

$$q_i = q_0$$

$$q_f = q_2$$

$$q_0 \xrightarrow{a} q_1$$

$$q_1 \xrightarrow{b} q_2$$

$$q_2 \xrightarrow{a} q_1$$

Then, we have the following traces:

$$\tau_0 = \langle (q_0, ab), (q_1, b), (q_2, \epsilon) \rangle$$

$$\tau_1 = \langle (q_0, abab), (q_1, bab), (q_2, ab), (q_1, b), (q_2, \epsilon) \rangle$$

$$\tau_2 = \langle (q_0, ababab), (q_1, babab), (q_2, abab), (q_1, bab) \rangle$$

$$\tau_3 = \langle (q_0, abaaa), (q_1, baaa), (q_2, aaa), (q_1, aa) \rangle$$

Then:

- $\tau_0, \tau_1$  are initial traces, reaching a final state
- $\tau_2$  is an initial trace, and is not maximal
- $\tau_3$  reaches a blocking state, but not a final state

## Example: $\lambda$ -term

We consider  $\lambda$ -term  $\lambda y \cdot ((\lambda x \cdot y)((\lambda x \cdot x x) (\lambda x \cdot x x)))$ , and show two traces generated from it (at each step the reduced lambda is shown in red):

$$\tau_0 = \langle \lambda y \cdot ((\lambda x \cdot y)((\lambda x \cdot x x) (\lambda x \cdot x x))), \\ \lambda y \cdot y \rangle$$

$$\tau_1 = \langle \lambda y \cdot ((\lambda x \cdot y)((\lambda x \cdot x x) (\lambda x \cdot x x))), \\ \lambda y \cdot ((\lambda x \cdot y)((\lambda x \cdot x x) (\lambda x \cdot x x))), \\ \lambda y \cdot ((\lambda x \cdot y)((\lambda x \cdot x x) (\lambda x \cdot x x))) \rangle$$

Then:

- $\tau_0$  is a maximal trace; it reaches a blocking state (no more reduction can be done)
- $\tau_1$  can be extended for arbitrarily many steps ;  
the second part of the course will study **infinite traces**

# Example: imperative program

Similarly, we can write the traces of a simple imperative program:

$\ell_0$ : $x := 1$ ;	$\tau = \langle$	$(\ell_0, \langle x = 6, y = 8 \rangle),$	$(\ell_1, \langle x = 1, y = 8 \rangle),$
$\ell_1$ : $y := 0$ ;		$(\ell_2, \langle x = 1, y = 0 \rangle),$	$(\ell_3, \langle x = 1, y = 0 \rangle),$
$\ell_2$ : <b>while</b> ( $x < 4$ ) {		$(\ell_4, \langle x = 1, y = 1 \rangle),$	$(\ell_5, \langle x = 2, y = 1 \rangle),$
$\ell_3$ : $y := y + x$ ;		$(\ell_3, \langle x = 2, y = 1 \rangle),$	$(\ell_4, \langle x = 2, y = 3 \rangle),$
$\ell_4$ : $x := x + 1$ ;		$(\ell_5, \langle x = 3, y = 3 \rangle),$	$(\ell_3, \langle x = 3, y = 3 \rangle),$
$\ell_5$ :     }		$(\ell_4, \langle x = 3, y = 6 \rangle),$	$(\ell_5, \langle x = 4, y = 6 \rangle),$
$\ell_6$ : (final program point)		$(\ell_6, \langle x = 4, y = 6 \rangle)$	$\rangle$

- very **precise** description of what the program does...
- ... but **quite cumbersome**

# Outline

1 Transition systems and small step semantics

2 Traces semantics

- Definitions
- Finite traces semantics
- Fixpoint definition
- Compositionality
- Infinite traces semantics

3 Summary

## Towards a fixpoint definition

We consider again our contrived transition system

$$\mathcal{S} = (\{a, b, c, d\}, \{(a, b), (b, a), (b, c)\})$$

Traces **by length**:

$i$	traces of length $i$
0	$\epsilon$
1	$\langle a \rangle, \langle b \rangle, \langle c \rangle, \langle d \rangle$
2	$\langle a, b \rangle, \langle b, a \rangle, \langle b, c \rangle$
3	$\langle a, b, a \rangle, \langle b, a, b \rangle, \langle a, b, c \rangle$
4	$\langle a, b, a, b \rangle, \langle b, a, b, a \rangle, \langle b, a, b, c \rangle$

**Like the automaton in lecture 1, this suggests a least fixpoint definition:** traces of length  $i + 1$  can be derived from the traces of length  $i$ , by adding a transition

# Trace semantics fixpoint form

We define a **semantic function**, that computes **the traces of length  $i + 1$  from the traces of length  $i$**  (where  $i \geq 1$ ), and **adds the traces of length 1**:

## Finite traces semantics as a fixpoint

Let  $\mathcal{I} = \{\epsilon\} \cup \{\langle s \rangle \mid s \in \mathbb{S}\}$ . Let  $F_*$  be the function defined by:

$$\begin{aligned}
 F_* : \mathcal{P}(\mathbb{S}^*) &\longrightarrow \mathcal{P}(\mathbb{S}^*) \\
 X &\longmapsto \mathcal{I} \cup \{\langle s_0, \dots, s_n, s_{n+1} \rangle \mid \langle s_0, \dots, s_n \rangle \in X \wedge s_n \rightarrow s_{n+1}\}
 \end{aligned}$$

Then,  $F_*$  is **continuous** and thus has a least-fixpoint and:

$$\text{lfp } F_* = \llbracket \mathbb{S} \rrbracket^* = \bigcup_{n \in \mathbb{N}} F_*^n(\emptyset)$$

# Fixpoint definition: proof (1), fixpoint existence

First, we prove that  $F_*$  is **continuous**.

Let  $\mathcal{X} \subseteq \mathcal{P}(\mathbb{S}^*)$  such that  $\mathcal{X} \neq \emptyset$  and  $A = \bigcup_{U \in \mathcal{X}} U$ . Then:

$$\begin{aligned}
 & F_*(\bigcup_{X \in \mathcal{X}} X) \\
 &= \mathcal{I}U\{\langle s_0, \dots, s_n, s_{n+1} \rangle \mid (\langle s_0, \dots, s_n \rangle \in \bigcup_{U \in \mathcal{X}} U) \wedge s_n \rightarrow s_{n+1}\} \\
 &= \mathcal{I}U\{\langle s_0, \dots, s_n, s_{n+1} \rangle \mid \exists U \in \mathcal{X}, \langle s_0, \dots, s_n \rangle \in U \wedge s_n \rightarrow s_{n+1}\} \\
 &= \mathcal{I}U\left(\bigcup_{U \in \mathcal{X}} \{\langle s_0, \dots, s_n, s_{n+1} \rangle \mid \langle s_0, \dots, s_n \rangle \in U \wedge s_n \rightarrow s_{n+1}\}\right) \\
 &= \bigcup_{U \in \mathcal{X}} (\mathcal{I}U\{\langle s_0, \dots, s_n, s_{n+1} \rangle \mid \langle s_0, \dots, s_n \rangle \in U \wedge s_n \rightarrow s_{n+1}\}) \\
 &= \bigcup_{U \in \mathcal{X}} F_*(U)
 \end{aligned}$$

In particular, this is true for any increasing chain  $\mathcal{X}$  (here, we considered any non empty family), hence  $F_*$  is continuous.

As  $(\mathcal{P}(\mathbb{S}^*), \subseteq)$  is a CPO, the continuity of  $F_*$  entails the **existence of a least-fixpoint** (Kleene theorem); moreover, it implies that:

$$\text{lfp } F_* = \bigcup_{n \in \mathbb{N}} F_*^n(\emptyset)$$

# Fixpoint definition: proof (2), fixpoint equality

We now show **that  $\llbracket \mathcal{S} \rrbracket^*$  is equal to  $\text{lfp } F_*$** , by showing the property below, by induction over  $n$ :

$$\forall k < n, \langle s_0, \dots, s_k \rangle \in F_*^n(\emptyset) \iff \langle s_0, \dots, s_k \rangle \in \llbracket \mathcal{S} \rrbracket^*$$

- at rank 0, only trace  $\epsilon$  needs to be considered, and its case is trivial
- at rank  $n + 1$ , we need to consider both traces of length 1 (the case of which is trivial) and traces of length  $n + 1$  for some integer  $n \geq 1$ :

$$\begin{aligned} \langle s_0, \dots, s_k, s_{k+1} \rangle &\in \llbracket \mathcal{S} \rrbracket^* \\ \iff \langle s_0, \dots, s_k \rangle &\in \llbracket \mathcal{S} \rrbracket^* \wedge s_k \rightarrow s_{k+1} \\ \iff \langle s_0, \dots, s_k \rangle &\in F_*^n(\emptyset) \wedge s_k \rightarrow s_{k+1} \quad (k < n \text{ since } k + 1 < n + 1) \\ \iff \langle s_0, \dots, s_k, s_{k+1} \rangle &\in F_*^{n+1}(\emptyset) \end{aligned}$$

# Trace semantics fixpoint form: example

**Example**, with the same simple transition system  $\mathcal{S} = (\mathbb{S}, \rightarrow)$ :

- $\mathbb{S} = \{a, b, c, d\}$
- $\rightarrow$  is defined by  $a \rightarrow b$ ,  $b \rightarrow a$  and  $b \rightarrow c$

Then, the first iterates are:

$$\begin{aligned}
 F_*^0(\emptyset) &= \emptyset \\
 F_*^1(\emptyset) &= \{\epsilon, \langle a \rangle, \langle b \rangle, \langle c \rangle, \langle d \rangle\} \\
 F_*^2(\emptyset) &= F_*^1(\emptyset) \cup \{\langle b, a \rangle, \langle a, b \rangle, \langle b, c \rangle\} \\
 F_*^3(\emptyset) &= F_*^2(\emptyset) \cup \{\langle a, b, a \rangle, \langle b, a, b \rangle, \langle a, b, c \rangle\} \\
 F_*^4(\emptyset) &= F_*^3(\emptyset) \cup \{\langle b, a, b, a \rangle, \langle a, b, a, b \rangle, \langle b, a, b, c \rangle\} \\
 F_*^5(\emptyset) &= F_*^4(\emptyset) \cup \{\langle a, b, a, b, a \rangle, \langle b, a, b, a, b \rangle, \langle a, b, a, b, c \rangle\} \\
 F_*^6(\emptyset) &= \dots
 \end{aligned}$$

The traces of  $\llbracket \mathcal{S} \rrbracket^*$  of length  $n + 1$  appear in  $F_*^n(\emptyset)$

# Outline

1 Transition systems and small step semantics

2 Traces semantics

- Definitions
- Finite traces semantics
- Fixpoint definition
- Compositionality
- Infinite traces semantics

3 Summary

# Notion of compositional semantics

The traces semantics definition we have seen is **global**:

- the **whole system** defines a **transition relation**
- we **iterate** this relation until we get a fixpoint

Though, a **modular** definition would be nicer, to allow reasoning on program fragments, or derive properties of a program from properties of its pieces...

**Can we derive a more modular expression of the semantics ?**

# Notion of compositional semantics

## Observation: programs often have an inductive structure

- **$\lambda$ -terms** are defined by induction over the syntax
- **imperative programs** are defined by induction over the syntax
- **there are exceptions:** our MIPS language does not naturally look that way

## Definition: compositional semantics

A semantics  $\llbracket \cdot \rrbracket$  is said to be **compositional** when the semantics of a program can be defined as a function of the semantics of its parts, i.e.,

When program  $\pi$  writes down as  $C[\pi_0, \dots, \pi_k]$  where  $\pi_0, \dots, \pi_k$  are its components, there exists a function  $F_C$  such that

$\llbracket \pi \rrbracket = F_C(\llbracket \pi_0 \rrbracket, \dots, \llbracket \pi_k \rrbracket)$ , where  $F_C$  depends only on syntactic construction  $F_C$ .

## Case of a simplified imperative language

Case of **a sequence of two instructions**  $b \equiv l_0 : i_0; l_1 : i_1; l_2$ :

$$\begin{aligned} \llbracket b \rrbracket^* &= \llbracket i_0 \rrbracket^* \cup \llbracket i_1 \rrbracket^* \\ &\cup \{ \langle s_0, \dots, s_m \rangle \mid \exists n \in \llbracket 0, m \rrbracket, \\ &\quad \langle s_0, \dots, s_n \rangle \in \llbracket i_0 \rrbracket^* \wedge \langle s_n, \dots, s_m \rangle \in \llbracket i_1 \rrbracket^* \} \end{aligned}$$

This amounts to **concatenating** traces of  $\llbracket i_0 \rrbracket^*$  and  $\llbracket i_1 \rrbracket^*$  that share a state in common (necessarily at point  $l_1$ ).

Cases of **a condition, a loop**: **similar**

- by **concatenation** of traces around **junction points**
- by doing a **least-fixpoint computation** over loops

We can provide a compositional semantics for our simplified imperative language

# Case of $\lambda$ -calculus

Case of a  $\lambda$ -term  $t = (\lambda x \cdot u) v$ :

- executions may start with a reduction in  $u$
- executions may start with a reduction in  $v$
- executions may start with the reduction of the head redex
- an execution may mix reductions steps in  $u$  and  $v$  in an arbitrary order

No nice compositional trace semantics of  $\lambda$ -calculus...

# Outline

1 Transition systems and small step semantics

2 Traces semantics

- Definitions
- Finite traces semantics
- Fixpoint definition
- Compositionality
- Infinite traces semantics

3 Summary

# Non termination

## Can the finite traces semantics express non termination ?

Consider the case of our contrived system:

$$\mathbb{S} = \{a, b, c, d\} \quad (\rightarrow) = \{(a, b), (b, a), (b, c)\}$$

### System behaviors:

- this system clearly **has non-terminating behaviors**:  
it can loop from  $a$  to  $b$  and back forever
- the finite traces semantics does show **the existence of this cycle** as there exists an **infinite chain of finite traces for the prefix order**  $\prec$ :

$$\langle a, b \rangle, \langle a, b, a \rangle, \langle a, b, a, b \rangle, \langle a, b, a, b, a \rangle, \dots \in \llbracket \mathcal{S} \rrbracket^*$$

- though, the existence of this chain is **not very obvious**

Thus, we now define a semantics made of infinite traces

# Semantics of infinite traces

We consider a transition system  $\mathcal{S} = (\mathbb{S}, \rightarrow)$

## Definition

The **infinite traces semantics**  $\llbracket \mathcal{S} \rrbracket^\omega$  is defined by:

$$\llbracket \mathcal{S} \rrbracket^\omega = \{ \langle s_0, \dots \rangle \in \mathbb{S}^\omega \mid \forall i, s_i \rightarrow s_{i+1} \}$$

**Infinite traces starting from an initial state** (considering  $\mathcal{S} = (\mathbb{S}, \rightarrow, \mathbb{S}_I, \mathbb{S}_F)$ ):

$$\{ \langle s_0, \dots \rangle \in \llbracket \mathcal{S} \rrbracket^\omega \mid s_0 \in \mathbb{S}_I \}$$

## Example:

- contrived transition system defined by

$$\mathbb{S} = \{a, b, c, d\} \quad (\rightarrow) = \{(a, b), (b, a), (b, c)\}$$

- the infinite traces semantics contains **exactly two** traces

$$\llbracket \mathcal{S} \rrbracket^\omega = \{ \langle a, b, \dots, a, b, a, b, \dots \rangle, \langle b, a, \dots, b, a, b, a, \dots \rangle \}$$

# Fixpoint form

Can we also provide a fixpoint form for  $[[S]]^\omega$  ?

Intuitively,  $\langle s_0, s_1, \dots \rangle \in [[S]]^\omega$  if and only if  $\forall n, s_n \rightarrow s_{n+1}$ , i.e.,

$$\forall n \in \mathbb{N}, \forall k \leq n, s_k \rightarrow s_{k+1}$$

Let  $F_\omega$  be defined by:

$$\begin{aligned} F_\omega : \mathcal{P}(S^\omega) &\longrightarrow \mathcal{P}(S^\omega) \\ X &\longmapsto \{ \langle s_0, s_1, \dots, s_n, \dots \rangle \mid \langle s_1, \dots, s_n, \dots \rangle \in X \wedge s_0 \rightarrow s_1 \} \end{aligned}$$

Then, we can show by induction that:

$$\begin{aligned} \sigma \in [[S]]^\omega &\iff \forall n \in \mathbb{N}, \sigma \in F_\omega^n(S^\omega) \\ &\iff \bigcap_{n \in \mathbb{N}} F_\omega^n(S^\omega) \end{aligned}$$

# Fixpoint form of the semantics of infinite traces

## Infinite traces semantics as a fixpoint

Let  $F_\omega$  be the function defined by:

$$\begin{aligned}
 F_\omega : \mathcal{P}(\mathbb{S}^\omega) &\longrightarrow \mathcal{P}(\mathbb{S}^\omega) \\
 X &\longmapsto \{ \langle s_0, s_1, \dots, s_n, \dots \rangle \mid \langle s_1, \dots, s_n, \dots \rangle \in X \wedge s_0 \rightarrow s_1 \}
 \end{aligned}$$

Then,  $F_\omega$  is  $\cap$ -continuous and thus has a **greatest-fixpoint**; moreover:

$$\mathbf{gfp} F_\omega = \llbracket \mathcal{S} \rrbracket^\omega = \bigcap_{n \in \mathbb{N}} F_\omega^n(\mathbb{S}^\omega)$$

### Proof sketch:

- the  $\cap$ -continuity proof is similar as for the  $\cup$ -continuity of  $F_*$
- by the dual version of Kleene's theorem,  $\mathbf{gfp} F_\omega$  exists and is equal to  $\bigcap_{n \in \mathbb{N}} F_\omega^n(\mathbb{S}^\omega)$ , i.e. to  $\llbracket \mathcal{S} \rrbracket^\omega$  (similar induction proof)

# Fixpoint form of the infinite traces semantics: iterates

**Example**, with the same simple transition system:

- $\mathbb{S} = \{a, b, c, d\}$
- $\rightarrow$  is defined by  $a \rightarrow b$ ,  $b \rightarrow a$  and  $b \rightarrow c$

Then, the first iterates are:

$$F_{\omega}^0(\mathbb{S}^{\omega}) = \mathbb{S}^{\omega}$$

$$F_{\omega}^1(\mathbb{S}^{\omega}) = \langle a, b \rangle \cdot \mathbb{S}^{\omega} \cup \langle b, a \rangle \cdot \mathbb{S}^{\omega} \cup \langle b, c \rangle \cdot \mathbb{S}^{\omega}$$

$$F_{\omega}^2(\mathbb{S}^{\omega}) = \langle b, a, b \rangle \cdot \mathbb{S}^{\omega} \cup \langle a, b, a \rangle \cdot \mathbb{S}^{\omega} \cup \langle a, b, c \rangle \cdot \mathbb{S}^{\omega}$$

$$F_{\omega}^3(\mathbb{S}^{\omega}) = \langle a, b, a, b \rangle \cdot \mathbb{S}^{\omega} \cup \langle b, a, b, a \rangle \cdot \mathbb{S}^{\omega} \cup \langle b, a, b, c \rangle \cdot \mathbb{S}^{\omega}$$

$$F_{\omega}^4(\mathbb{S}^{\omega}) = \dots$$

## Intuition

- at iterate  $n$ , prefixes of length  $n + 1$  match the traces in the infinite semantics
- only  $\langle a, b, \dots, a, b, a, b, \dots \rangle$  and  $\langle b, a, \dots, b, a, b, a, \dots \rangle$  belong to *all* iterates

# Outline

- 1 Transition systems and small step semantics
- 2 Traces semantics
- 3 Summary

# Summary

## We have discussed today:

- **small-step / structural operational semantics:**  
individual program steps
- **big-step / natural semantics:**  
program executions as sequences of transitions
- their **fixpoint definitions** and properties  
will play a great role to design verification techniques

## Next lectures:

- another family of semantics, **more compact** and **compositional**
- **semantic program** and **proof methods**
